Thirty-six per cent. of the American intake of protein is in the form of grain, 26 per cent. in meats, and 20 per cent. in dairy products. Of fat, 51 per cent. is furnished by meats, 27 per cent. by dairy products, and 12 per cent. by vegetable oils and nuts. Of carbohydrates, 56 per cent. is furnished by grains and 26 per cent. by sugars. Of total energy, 35 per cent. comes from grains, 22 per cent. from meats, 15 per cent. from dairy products, and 13 per cent. from sugars. These four groups contribute 85 per cent. of the total energy value.

The effects of the food economy campaign and the food administration in 1917–18 are of interest. The total consumption of food increased, but not in proportion to the population; the consumption of meat practically did not increase at all, and the consumption of grain only 1 per cent. The great increases were in the consumption of vegetables, of oils and nuts, and of oleomargarine, amounting respectively to 30 per cent., 29 per cent., and 116 per cent over the averages of the preceding six years. The increase in the two former groups may have been due to the activity of

the Food Administration in urging the consumption of these commodities to relieve the pressure upon wheat and animal products. The increased consumption of oleomargarine was no doubt due to a favourable price in comparison with that of butter and lard.

Prof. Pearl provides a summary of daily consumption per "man," which again brings out the uniformity from year to year. The largest figure is 4361 Calories in 1913–14, and the smallest 4211 in 1916–17. The average figures are: 121 grams of protein, 169 grams of fat, and 542 grams of carbohydrate, yielding 4290 Calories. Assuming that 5 per cent. of protein, 20 per cent. of carbohydrate, and 25 per cent. of fat are lost in the wastage of edible substances, the *per capita* average of ingested food becomes:—Protein, 114 grams; fat, 127 grams; and carbohydrate, 433 grams, yielding 3424 Calories. These final figures are in good accord with the results of dietetic studies both in America and in England. Prof. Pearl justly remarks that "discussions of the minimum protein, fat, and carbohydrate requirements of a nation are in a considerable degree academic if they base themselves upon net consumption rather than gross consumption. A considerable excess over any agreed-upon minimum *physiological* requirements must always be allowed, because there will inevitably be, in fact, a margin between actual gross consumption and net physiological ingestion or utilisation."

The report is a useful contribution to knowledge. It is to be feared that since the armistice little attention has been devoted to the study of national dietetics in this country. During the war British physiologists made valuable experimental and statistical contributions to the subject; on the statistical side the work of the late Sir William Thompson, and on the experimental side that of Prof. Cathcart and his collaborators, deserve special mention. It is to be regretted that there is little prospect of the foundations then laid being built upon; it will be long indeed before the task of feeding the nation ceases to cause anxiety and to merit scientific elucidation.

M. G.

Engineering Research in the U.S.A.

THE problem of co-ordinating the interests and activities of the various engineering institutions and societies has been subject to much discussion in this country. In America this problem was largely solved by the establishment in 1904 of the United Engineering Society, which combined the interests of four founders' societies, namely, the American Society of Civil Engineers and the American Institutes of Mining and Metallurgical Engineers, Mechanical Engineers, and Electrical Engineers. The United Engineering Society now numbers some forty thousand members, and its administration comprises three principal departments, namely, the library board, the engineering council, and the engineering foundation. The last-named department is of particular interest, and is directed to the furtherance of research in science and engineering.

The engineering foundation was established as a result of a gift of 200,000 dollars by Mr. Ambrose Swasey, this sum being used as the nucleus of a fund the income of which was to be devoted to research or for the advancement in any other manner of the profession of engineering and the good of mankind. This first gift was made in 1914, and in September, 1918, Mr. Swasey added a further sum of 100,000 dollars to the endowment.

The donor is an engineer and manufacturer, and president of the Warner-Swasey Co., of Cleveland, Ohio, a firm manufacturing fine tools and astronomical and other instruments of precision. Mr. Swasey is a member of most of the American engineering societies, and of several English scientific societies, including the Royal Astronomical Society. He is the author of a number of papers read before American engineering societies.

For all practical purposes the engineering foundation is a professional trust organised along the lines of the Carnegie, Rockefeller, and Sage foundations. The facilities it provides have heretofore been devoted principally to engineering research, and its most notable work has been conducted through co-operation with the National Research Council, which is an organisation of men of science, engineers, and educators brought into being by the National Academy of Science at the request of President Wilson in 1916, and employed largely in the conduct of scientific investigations relating to anti-submarine and other war problems.

When the National Research Council was formed the administrators of the engineering foundation made themselves responsible for its financial support for a period of one year, and this brought into successful co-operation a body of engineering and scientific men in a comprehensive and practical manner.

Since July, 1919, the research work undertaken by the foundation has been of a very comprehensive nature. It has included, for example, preliminary researches on such subjects as a new hardness testing machine, the elimination of casting defects from steel, the uses of cadmium, the uses of alloy steels, Neumann bands in iron and steel, the heat treatment of carbon steel, electrical insulation, and substitute deoxidisers. A sum of 15,000 dollars a year for a period of two years has been voted for the conduct of research in the fatigue phenomena of metals in the laboratories of the engineering experiment station of the University of Illinois. From approximately fifty suggested subjects, the engineering foundation has also selected for investigation: (1) The wear of gears, (2) spray camouflage for ships, (3) the directive control of wireless communication, (4) weirs for the measurement of water, (5) the establishment of a testing station for large water-wheels and other large hydraulic equipment, and (6) the mental hygiene of industry.

These investigations are now all in progress or have been completed. Particular attention has been given to research relating to mental hygiene in industry, the objects of the research being to develop or discover methods for adapting psychopathetic individuals to usefulness in industry.

Realising, further, that mental hygiene dealt with only one of the many elements of the industrial *personnel* problem, the foundation board, in association with the National Research Council, arranged for the appointment of a committee representative of anthropology, psychology, educational relations, industrial relations, engineering, and medicine to consider means for furthering the study of the problems of industrial employment.

Quite apart from such efforts, the engineering foundation has interested itself in an attempt to coordinate the activities of many of the very numerous societies and associations, some local, some national, having a bearing on engineering, and to harmonise their relations and aims. Up to the present, however, no active investigational work along these lines has been undertaken. While the foundation maintains the closest relationship with the divisions of engineering of the United Engineering Society and the National Research Council, it reserves the right to conduct under its own immediate direction such researches as may commend themselves to its membership.

The administration of the engineering foundation is conducted by sixteen members elected by the United Engineering Society, thirteen of whom must be members of the founder societies. Although finally organised only in the early part of 1915, the foundation has become thoroughly established, and is carrying on a most admirable work.

A. P. M. FLEMING.

African Softwoods for Pulp Production.

By A. H. UNWIN,

Late Senior Conservator of Forests, Nigeria.

ABOUT the year 1907, at the instigation of the late Sir Alfred Jones, an inquiry was addressed to the West African Colonies with regard to the softwoods suitable for paper or pulp production. As a result a list was compiled for the Benin country, which included some twenty species of whitewood. Since that date little or nothing has been done towards the solution of this problem. Nevertheless, much greater knowledge has been obtained of the softwoods of the West African Colonies—the Gambia, Sierra Leone, Gold Coast, Nigeria—and of West Africa generally.

Although baobab (*Andansonia digitata*) has been suggested as suitable, it is usually found rather remote from navigable waterways, and in such scattered quantities that it is doubtful if its exploitation will pay. On the other hand, the wood of the cotton-tree, *Eriodendron anfractuosum* and *E. orientale*, has been adversely reported upon, but it does not appear that very exhaustive experiments were made with either of these species. The ease of its production, the rapidity of its growth, and the softness of its wood would seem to commend the cotton-tree for pulp production. The wood of *Bombax buonopozense* may also be of use.

Perhaps a more suitable wood will be obtained from the African maple, *Triplochiton Johnsonii* and *T. nigericum*. The wood of both these species is of about the same hardness as that of spruce. It is of a similar colour, and the fibres are long. The tree is very prevalent, its reproduction easy in the proper localities, and its growth rapid. On average soil the trees reach pulp-wood size within ten years, and there are many specimens even in seven years.

In certain localities the occurrence of *Sterculia Barterii* is such as to redden the hill-sides with its flowers in March. The growth of the tree is very rapid, and the wood is fibrous and porous. The tree will attain pulp-wood size in five years. In suitable localities the natural reproduction from mature trees is rapidly filling the whole forest.

Other Sterculiæ, such as *tomentosa*, *rhinopetala*, and *tragacantha*, might be used. Of these the last-named appears to be the most suitable. It is also very prevalent, and grows rapidly. The wood of *Sterculia rhinopetala* may prove to be a little hard, but with modern means of pulping it may be possible to use all these species at the same time.

The quantity of bamboo on the West Coast of Africa is negligible, though the area of its distribution is gradually widening.

The Albizzias usually produce in their younger stages a whitish-yellow softwood. Most species grow very fast, and would yield pulp-wood within ten years. The wood shows long fibres. Owing to the prevalence of the tree in the forests, there would be no difficulty as to the quantity. The wood of *Terminalia superba* should prove of value, though its brownish tinge may have to be removed in order to make the best-coloured pulp. It is prevalent and its growth is rapid.

Another very common tree is *Alstonia congensis*, which is often found in the swamps as well as in the moist forests. Its growth is very rapid, and it would yield pulp-wood in seven years. Owing to its prevalence, this softwood with its longish fibre should prove of value.

The wood of *Ricinodendron Heudelotti* appears to be suitable, though the colour is dull grey-brown. The tree is very prevalent, and its natural regeneration prolific. It reaches pulp-wood size within a period of seven to ten years. *Pycanthus kombo* is another tree which appears to yield a suitable species of timber. It is very prevalent, the wood is soft and fibrous, and natural reproduction is great. Even the much-despised *Musanga Smithii* might on occasion be used to supplement inadequate supplies of other pulp-wood timbers. Near the rivers in some districts there is a common tree named Otu, which is planted by the natives. It yields a soft whitewood which has a longish fibre.

With the great shortage of paper-pulp it appears that the utilisation of these West African species of trees should be undertaken as soon as possible. Naturally, it will mean a good deal of experimental work, but with the experience already gained in Canada and Norway and Sweden it should be possible to produce pulp below existing cost. Although African labour is expensive as compared with Indian or Burman, it has proved itself thoroughly adaptable to training in the use of complicated machinery such as that employed in shipbuilding and in oil- and saw-mills.

With a population of about sixteen millions of people in Nigeria alone, it has been found possible gradually to obtain sufficient men for a new industry.

Effect of Topography on Precipitation in Japan.

CONSIDERABLE attention has been directed recently to the subject of the orographical distribution of rainfall, and results obtained in different places are liable to lead to general deductions, not only independent, if not quite contradictory, but also, on the face of them, improbable. We may instance an alleged connection between Indian monsoon intensity and the extent of local water surfaces, and also M. Mathias' cartographical demonstration that the increase of precipitation with altitude is directly dependent on the latitude, at any rate in France. Mr. Carle Salter's lecture to the Institution of Water Engineers on the relation of rainfall to configuration gave little ground for suspecting either of these possibilities.

At first sight, Prof. Terada's contribution in the Journal of the College of Science, Tokyo Imperial University (vol. xli., art. 5), appears to be only a supplement to previous work of Profs. Nakamura and Fujiwhara, but one or two comparatively fresh notes are struck. Prof. Omori had previously found a correlation between earthquake frequency in some districts and precipitation in others. This is now described by Prof. Terada as a case more of parallelism than of cause and effect, for he prefers to attribute both phenomena to barometric changes rather than to associate the instability of the soil with percolation. His main purpose, however, is to study the effect of the discontinuity of wind velocity on land and sea, and for this purpose he divides Japan into six districts, three facing the ocean and three the Japan Sea, and in each district chooses two or three stations near the coast.

The three "ocean" divisions show a marked increase in rainfall with decreasing latitude, but on the con-

tinental side the middle section is the wettest. Moreover, taking the divisions in pairs, there is a marked difference in the comparison. In the northern and central pairs the "continental" section is the drier, while in the remaining pair the difference is greater and also reversed in sign. Prof. Terada connects this anomaly with a possible "centre of action" controlled by the position of the Korean promontory, but it seems to be quite possible that he has overlooked the probable effect of the contour of the land itself. A glance at the map will show that his southernmost "ocean" division is practically outside the main island, which includes the northern and central divisions and the greater part of the continental southern division, so that we should naturally expect some sort of anomaly in that region, apart from the fact that the vertebral line of division, which is not far from a meridian in the north, tends to become more nearly a parallel in the south.

The author has adopted a good plan in using percentages instead of totals to prevent undue emphasis being placed on the wettest periods and places.

W. W. B.

Economic Entomology in the Philippines.[1]

A CONSIDERABLE portion of the Bulletin before us is the outcome of work undertaken with the definitely economic object of procuring and transporting to the battlefield natural enemies of the beetle *Anomala orientalis*, which, by reason of the havoc wrought in the larval stage on the roots of the sugar-cane, is a serious pest in the plantations, and was causing heavy losses in the Island of Oahu, Hawaii. It is gratifying to learn that the quest of the entomologists was entirely successful, and that through their labours the foe appears to have been vanquished, and thereby all mankind benefited in the saving of large quantities of one of our most valuable articles of food. The ally which the entomological staff summoned to the aid of the sugar-planters was the "wasp" *Scolia manilae*. It is perhaps prudent here to indicate that the term "wasp studies" must not be understood to apply solely to the true Diplopterous wasps, the Vespidæ; it is used in this publication as a convenient term including many families of aculeate Hymenoptera other than the bees.

Scolia manilae is a small black and yellow wasp that occurs abundantly in the Philippines. The females possess the power of detecting the presence of certain subterranean beetle grubs, and, having located their victim, dig down to it and deposit on its ventral surface an egg from which there soon emerges a larva that devours the beetle grub. The plan of campaign was simple. At Los Baños quantities of females of *Scolia manilae* were captured and placed in suitable vessels in which had been placed beetle grubs of appropriate age, and a sprig of foliage moistened with water and honey for the personal benefit of the wasps. Most of the grubs duly received an egg; those so favoured were placed in clay cells which were packed in soil in a tightly closed can, and then shipped to Oahu. Here the Scoliæ of the next generation emerged and were liberated. They established themselves with such success and increased so rapidly that they are now more abundant near Honolulu than at their native place, Los Baños, while the pest *Anomala orientalis* is vanishing so satisfactorily as to cause wonder how the wasp maintains itself.

The authors describe and figure twenty-six new species belonging to several different families of "wasps"; and the bionomics of these and others are narrated with great detail by Dr. Williams. His observations show that many species of these "wasps" are of economic importance in keeping in check the numbers of harmful insects, and suggest that an important line of research is here open to the field-naturalist. From the purely scientific point of view, perhaps the most interesting feature of the Bulletin is the frequency with which instincts and behaviour that are characteristic of the most highly developed social wasps manifest themselves sporadically and in an incipient fashion among these solitary species. So much is this the case that it becomes almost possible to construct a gradually ascending series from the simplest to the most highly specialised. Commencing with species that differ but little in habits from the Ichneumonidæ, stinging and only temporarily paralysing their victim in order the better to attach their egg, but constructing no nest or burrow of any description, we may pass on to those that dig burrows or build nests either unaided or in company with a few other individuals, and reach the climax in the elaborate domestic arrangements and architecture of our familiar social wasps and hornets.

Report of Work of the Experiment Station of the Hawaiian Sugar Planters' Association. Entomological Series. Bulletin No. 14. Pp. 186+106 figs. (Honolulu, December, 1919.)

Climate of the Netherlands.

THE Royal Netherlands Meteorological Institute has recently issued, as publication No. 102, "The Climate of the Netherlands with Respect to Air Temperature," by Dr. Ch. M. A. Hartman. Many years have elapsed since any previous discussion of air temperature in the Netherlands was undertaken. The stations yielding observations only for recent years have been compared with the stations available for longer periods, by which, together with the aid of stations affording hourly observations, special corrections have been found for each month and for each station required to secure the true temperature from observations at the hours of 8, 2, and 7. At Zwanenburg, situated midway between Amsterdam and Haarlem, there is a series of observations from 1743 to 1860, and at De Bilt observations are available from 1849 to 1917. The annual variation is given for twenty-four years from 1894 to 1917 inclusive at twelve stations; the range of temperature varies with latitude and with an increased distance from the sea. Diurnal variation is much affected by the influence of the sea, which suggests the difficulty of obtaining a true mean temperature from a combination of, say, three hours, 8, 2, and 7, and of maintaining the same hours in winter and in summer, but a change of hours is recognised as not practicable. The highest temperatures observed are 99° F. and 97° F. at Maestricht respectively on August 4, 1857, and July 28, 1911, and 97° F. at Oudenbosch on June 8, 1915. The lowest readings are −8° F. at Winterswijk on February 7, 1895, and at Katwijk-on-Rhine on February 14, 1895. Frequency of different temperatures is given for several stations and for all months, and the occurrences of diurnal variations of temperature for each degree Centigrade are tabulated, also the diurnal range for each of the twenty-four hours. One of the many tables shows the temperatures which occur each month, with the different directions of the wind.

The Present Condition of the Aborigines of Central Australia.

INFORMATION lately received in this country discloses an appalling condition of affairs among the aborigines of the interior of Australia. The whole population is thoroughly polluted with disease, both tubercular and venereal, and the north-eastern tribes are doomed. It is anticipated that another ten years will see the last of such interesting tribes as the Dieri, Yanntowanta, Ngameni, and Nauroworka. This is largely due to contact with the lower elements of European and immigrant Asiatic civilisation. Misdirected kindness, however, is also, to some extent, responsible. A liberal supply of Government blankets has been distributed among the tribes; they wear the blankets when working in the sun, and then, when thoroughly overheated, sleep on the ground; pneumonia follows as a natural consequence. Another cause of their disappearance is due to the difficulties attendant on food-supply. The game on which they subsist is killed off or driven away by the encroachment of civilisation. Distress from this cause has recently been aggravated by severe drought. The extent of the ravages arising from these various causes may be gauged by the fact that half a century ago it was estimated that there were 12,000 aborigines within 180 miles north and 200 miles east of Adelaide, and now there are not more than about 120 in that area. In the early eighties of last century Gason stated that if steps were not taken, multiplication of the aborigines would result in the disappearance of the European population, yet in this same area of which he wrote it is now estimated that at the outside there are not more than 2000.

The deplorable condition of the aboriginal population was discovered owing to the fact that during the war a number of expeditions were sent out to Central and Northern Australia in connection with the search for minerals for use in munition work. Dr. Herbert Basedow, a Protector of Aborigines in the service of the South Australian Government, who was a member of several of these expeditions, was then brought into close contact with the tribes. On his return to Adelaide at the end of the war he endeavoured to arouse the public conscience by a meeting in the Town Hall, at which he gave an undisguised account of what he had seen. As a result 500*l.* has been subscribed, and an equal amount promised by the Government, for the provision of medical relief. This sum has enabled Dr. Basedow to get together a small relief party. His first expedition on this work followed the course of the Strzelecki to Innamincka, thence along the Cooper, across the boundary into Queensland. Recrossing the border, the party visited Cordillo, Cadelga, Ringamurra, and Birdsville, thence following the Diamantina to Hergott Springs. One of the severest droughts on record was raging at the time; the heat was terrific—the average temperature was 116°–118° F.—and sand-storms blew for forty-eight hours at a time. No fewer than seven horses were abandoned exhausted along the route from Diamantina to Hergott Springs. The condition of the aborigines along the route is described by Dr. Basedow as "shocking." Dr. Basedow has recently started on another expedition, on which he proposes to proceed along the head of the Australian Bight as far as Eucla, along the Nullarboi Plains to Port Augusta, thence northwards to Oodnadatta, and across the boundary to the McDonnel Ranges.

Valuable as is such provision of medical relief as is possible by these expeditions, it is obviously only a temporary palliative. One of the most effective of the measures adopted for the assistance of the aborigines, whether directly under State protection or not, in the neighbouring State of Western Australia has been the establishment by the Government of a regular medical service. Further, while undesirable Europeans and Asiatics are permitted to mingle without control with the natives, it is inevitable that diseases will continue their ravages unchecked. A movement, which is receiving influential support, has been set on foot to induce the Government of South Australia to proclaim the north-west corner of the State, including the Musgrave, Mann, and Tomkinson Ranges, as an absolute reservation. It is hoped that it may also be possible to secure from the Commonwealth and the Western Australian Governments the proclamation of the adjoining ranges of the Northern Territory and Western Australia as strict reservations. This will probably be the last chance of preserving the Central Australian tribes from complete extinction.

E. N. FALLAIZE.

University and Educational Intelligence.

CAMBRIDGE.—Dr. Shillington Scales has been appointed University lecturer in medical radiology and electrology, and Mr. F. Lavington, Emmanuel College, Girdlers' lecturer in economics. Mr. J. Chadwick, Gonville and Caius College, has been elected to the Clerk Maxwell scholarship in experimental physics; Mr. H. F. Holden, St. John's College, to the Benn W. Levy research studentship in biochemistry; and Mr. A. J. Beamish, of Corpus Christi College, to the Wrenbury scholarship in economics.

The Marshall herbarium, comprising 23,000 sheets of British plants contained in dustproof oak cases, has been bequeathed to the University by the late Rev. E. S. Marshall, a keen and able field botanist, "unsurpassed as a collection of the critical flowering plants both in point of the number of interesting things he found and the care and industry he showed in selecting and pressing specimens of them."

EDINBURGH.—The foundation-stone of the new University buildings was laid by the King on Tuesday last, and the Queen accepted the honorary degree of LL.D.

LIVERPOOL.—The King, on the recommendation of the Chancellor and Council of the Duchy of Lancaster, has contributed 100 guineas to the appeal fund.

SHEFFIELD.—Dr. W. E. S. Turner has been appointed professor of glass technology, Mr. J. Husband professor of civil engineering, Dr. Mellanby professor of pharmacology, and Mr. R. E. Pleasance demonstrator in pathology.

By an inadvertence these appointments were given in NATURE of June 24 under the heading "Leeds."

PROF. F. FRANCIS has been appointed Pro-Vice-Chancellor of the University of Bristol in succession to Prof. Lloyd Morgan, who is about to resign the office.

DR. O. C. BRADLEY, principal of the Royal (Dick) Veterinary College, Edinburgh, has been elected president of the Royal College of Veterinary Surgeons in succession to Mr. J. McKinna.

A SCHOOL of medicine, surgery, and dentistry in connection with the University of Rochester, New York, has received an endowment of 1,800,000*l.* from the U.S. General Education Board and Mr. G. Eastman, of the Eastman Kodak Co. The contribution of the Board is 1,000,000*l.*, and that of Mr. Eastman 800,000*l.*

THE Eugenics Education Society has arranged for the holding of a summer school of eugenics and civics at Herne Bay College on July 31–August 14. The inaugural address will be delivered by Prof. A. Dendy on "Evolution in Human Progress," and there will be lectures and discussions on heredity, biology, eugenics, and sociology. The address of the society is 11 Lincoln's Inn Fields, W.C.2.

A SUMMER school of civics is to be held, under the auspices of the Civic Education League, at the Technical Institute, High Wycombe, Bucks, on July 31 to August 14. There are to be lectures on maternity and child welfare work, analytical psychology, and reconstruction problems; and courses on civics, sex education, local and central government, and anthropology have been arranged for. Further particulars can be obtained from the Secretary, Summer School of Civics, Leplay House, 65 Belgrave Road, S.W.1.

AN important American academic change is announced in the simultaneous resignations of Dr. G. Stanley Hall as president of Clark University and of Dr. Edmund C. Sanford as president of Clark College, and the appointment of Dr. Wallace W. Atwood as single head of both the University and the college. Dr. Atwood has been professor of physiography at Harvard since 1913, and is at present in the West in charge of a field expedition for the U.S. Geological Survey. In addition to his executive position, he will occupy the chair of regional and physical geography at Clark University. Dr. Stanley Hall is retiring in order that he may devote his whole time to the completion of several books on psychology which he has had in hand for a considerable period. Dr. Sanford will take the chair of psychology at Clark University, which Dr. Stanley Hall is vacating together with the presidency.

WE learn from *Science* that the following appropriations have recently been made by the U.S. General Education Board:—To the Washington University Medical School, St. Louis: For endowment, 250,000*l.*; for additional laboratory facilities and equipment, 14,000*l.* To Yale Medical School: For endowment (towards a total of 600,000*l.*), 200,000*l.* To Harvard Medical School: For improved facilities in obstetrics, 60,000*l.*; for the development of teaching in psychiatry, 70,000*l.* To Johns Hopkins Medical School: For development of a new department of pathology (towards a total of 120,000*l.*), 8000*l.* From the same source we learn that the Rockefeller Foundation has made appropriations as follow:—To Dalhousie University Medical School, Halifax: For buildings and equipment, 80,000*l.*; for endowments, 20,000*l.* To the Medical Research Foundation of Elisabeth, Queen of the Belgians, Brussels: For general purposes of medical research, 1,000,000 francs.

THE frontier between school and university has recently been the subject of much discussion. The Prime Minister's Committee on Science recommended that eighteen should be the normal age of entry from secondary schools to the universities, and in making that recommendation it was supported by all the witnesses who gave evidence on the subject. The Board of Education, by its efforts to standardise the Second School Examinations, and by watching the advanced courses given in schools, has done much to direct the studies of those who really are in the post-matriculation stage while at school; and the universities are faced, more than ever before, by the problem of how to arrange for students who enter with wide differences of attainment. There is but one solution: elasticity of organisation, both in the matter of examinations and in that of prescribed courses. During the past year a consultative council, on which were representatives of seven universities and four associations of school teachers, has been formed by the Association of Science Teachers in order to discuss the overlapping of school and university training. As a result, a resolution was sent to the various universities urging them "to recognise the value of the post-matriculation work in efficient schools by accepting the passing in subjects in one of the approved Second School Examinations as exempting from the corresponding subjects in the Intermediate Examination and the first Medical Examination of the University." The Association of Science Teachers is to be congratulated on organising the discussions which have led to this expression of opinion by a body well constituted to view the situation from opposite sides.

Societies and Academies.

LONDON.

Faraday Society, June 14.—Prof. A. W. Porter, vice-president, in the chair.—Dr. A. **Fleck** and T. **Wallace**: Conduction of electricity through fused sodium hydrate. The resistance to the passage of current through fused caustic soda and its rate of change with temperature have been examined by a direct-current method. In view of the difficulties of containing the soda in a non-conducting non-porous vessel, the experiments have been carried out in the centre of a large mass of soda. The decomposition voltage has been studied and found to be a variable quantity, decreasing at the rate of $2{\cdot}25\times10^{-3}$ volts per degree Centigrade rise in temperature. This figure differs from the previously published figure of $2{\cdot}95\times10^{-3}$. It has been found that when a current is passed through fused sodium hydrate between two sodium electrodes the current is always proportional to the applied E.M.F.—Dr. H. F. **Haworth**: The measurement of electrolytic resistances using alternating currents. An electrolytic cell acts like a capacity in series with a resistance. If this capacity and resistance be measured at various frequencies, they will be found to vary with the frequency. If the impedance of the cell is plotted vectorially with respect to the resistance for various frequencies, the locus is a straight line which cuts the resistance axis at infinite frequency. This gives the true resistance of the electrolyte.—J. L. **Haughton**: The measurement of electrical conductivity in metals and alloys at high temperatures. The study of the electrical conductivity of alloys has generally been carried out by measuring the conductivity of the alloys at room-temperature and plotting a curve connecting conductivity with composition, but much valuable information can be obtained by plotting the curve connecting the composition and temperature and using a series of such curves in the same way as the ordinary thermal curves. The paper describes a method which can be employed for this.—N. V. S. **Knibbs** and H. **Palfreeman**: The theory of electro-chemical chlorate and perchlorate formation. This paper is the outcome of a study of the electrolytic formation of chlorate and perchlorate based on recent large-scale operations. It aims at a presentation of the theory of the mechanism of chlorate and perchlorate formation and its application to their technical production. A series of investigations was undertaken in order to elucidate a number of doubtful points and to obtain data which were of importance in the technical control of the process.—J. B. **Firth**: Sorption of iodine by carbon. The sorption of iodine by carbon was studied over a period of five years; the forms of carbon used were lamp-black, blood carbon, sugar carbon, animal carbon,

coconut carbon from shell, and coconut carbon from fruit. The solvents used were chloroform and benzene. The activity of the carbon was shown to depend on its previous treatment. In all cases a rapid condensation takes place in the first few minutes, followed by a much slower sorption, which may continue for several years. The influence of the size of the carbon particles was also studied.—F. H. **Jeffery**: Electrolysis of solutions of sodium nitrite using a copper anode.—Dr. A. M. **Williams**: The pressure variation of equilibrium constant in dilute solution. The apparent discrepancy between the expressions of Planck and Rice rests on a misinterpretation of the latter's symbols. Another deduction is given.—Miss Nina **Hosali**: Models illustrating crystalline form and symmetry.

Linnean Society, June 17.—Dr. A. Smith Woodward, president, in the chair.—(The centenary of the death of Sir Joseph Banks.)—Dr. B. Daydon **Jackson**: Banks as a traveller.—Dr. A. B. **Rendle**: Banks as a patron of science.—J. **Britten**: Banks as a botanist.—Dr. A. Smith **Woodward**: Banks as a trustee of the British Museum of paramount power.

June 24.—Dr. A. Smith Woodward, president, in the chair.—Dr. C. J. F. **Skottsberg**: Botanical features of the Juan Fernandez group of islands.—Dr. R. J. **Tillyard**: The Cawthron Institute. This institute is to be situated in the city of Nelson, N.Z. An account was given of the early life and adventures of the founder, showing how he rose from a low estate to become a very wealthy man. In his later years he busied himself with philanthropic enterprises, and on his death it was found that he had left the greater portion of his fortune for the purpose of founding an institute of scientific research. After all claims had been paid, the Cawthron Trust was left with a capital of about 200,000*l*., which, wisely invested, would yield an income of about 11,000*l*. a year. Prof. T. H. Easterfield, of Wellington, N.Z., has been appointed director and chief of the chemical department, with Mr. T. H. Rigg, late of Rothamsted, working under him as agricultural chemist. In the biological department Miss K. M. Curtis has been appointed mycologist, and Mr. A. Philpott assistant entomologist. The library and museum are under the care of the curator, Mr. W. C. Davies. The activities of the institute will be directed towards scientific research, both pure and applied, with the view of benefiting the primary industries of New Zealand as a whole and of the Nelson Province in particular.

Aristotelian Society, June 21.—Mr. A. F. Shand in the chair.—Miss **Edgell**: Memory and conation. The views of three writers approaching the subject from the different viewpoints of philosophical psychology, biology, and psychiatry, viz. Prof. Ward, Dr. Semon, and Dr. Freud, were examined with reference to the question: Does memory require the recognition in mental life of a specific function, conation? Analysis shows that for Prof. Ward the activity of the subject of experience is essential both for the development of memory and for many of its manifestations. If the activity of the subject be understood as implying conation, then the author's theory of memory does involve conation. Dr. Semon, following Hering and Butler, regards memory as a function of all organic matter and its laws as laws of organic life. Nevertheless, in dealing with human memory Semon recognises "vividness" in imagery as essential for memory and association. Vividness is distinguished from intensity and made to depend on attention. The relation of attention to the laws of organic life is still obscure, and attention is treated as if it were an original force. The *rôle* of conation in the psychology of Dr. Freud is all-important. It is the conation of unconscious wish which is regarded as explanatory, if not of the fact of memory itself, at least of many of the phenomena of remembering and forgetting in everyday life.

PARIS.

Academy of Sciences, June 21.—M. Henri Deslandres in the chair.—The President announced the death of Adolphe Carnot, free member.—L. Torres Quevedo was elected correspondant for the section of mechanics in succession to the late M. Boulvin.—P. **Humbert**: Functions of the hyperparaboloid of revolution and hyperspherical functions.—J. **Villey**: The choice of the density of filling in the conception of aviation explosion motors.—R. **Jarry-Desloges**: Different phenomena observed on the planet Mars in the present opposition. Nix Olimpica was discovered by Schiaparelli in 1879, but no measurements have been taken since that date. Searches without result were made in 1881 by Schiaparelli, and in other observations between 1907 and 1916. The concordance between the measurements made at Milan in 1879 and those taken at Sétif in 1920 leave no room for doubt that Nix Olimpica has reappeared.—Mme. Paule **Collet**: Two modes of rectification of currents by galena.—E. **Berger**: Some reactions started by a primer. The use of a primer to start a chemical reaction instead of an external application of heat was first used by Goldschmidt, a mixture of barium peroxide and magnesium powder being employed to start the reaction between ferric oxide and powdered aluminium. The new primer proposed by the author consists of 60 per cent. potassium nitrate (or sodium nitrate) and 40 per cent. commercial calcium silicide. This burns with a very high temperature, and can be lit with a match. A description is given of the applications of this method to the production of phosphorus and arsenic, the reduction of the sulphates of the alkaline earths by phosphorus, and the preparation of the fluorides of silicon and boron.—A. **Recoura**: The constitution of the grey lilac chromium sulphate.—P. **Jolibois** and P. **Bouvier**: The precipitation of mercuric salts by sulphuretted hydrogen. The authors have applied the apparatus described in an earlier communication to the study of the reaction between mercuric chloride and hydrogen sulphide, the reaction being carried out with the two reagents in varying proportions. With excess of sulphuretted hydrogen the precipitate has the composition HgS; with the mercuric chloride in excess the precipitate (white) has the composition $2HgS,HgCl_2$, and there was no indication of the existence of any other intermediate compound.—P. **Chevenard**: The thermal change of the elastic properties of nickel-steels. The results of experiments on twenty-eight alloys of iron and nickel are given graphically in two diagrams.—A. de G. **Rocasolano**: The catalytic decomposition of solutions of hydrogen peroxide by colloidal platinum. Bredig and his pupils concluded from their experimental studies of this reaction that it was monomolecular. The author has used electrosols of platinum as catalyst, and comes to the conclusion that the reaction in this case is not monomolecular or of the first order. During the reaction the catalyst is changed. If some of this altered catalyst is added to a fresh quantity of hydrogen peroxide, the ensuing reaction is now monomolecular.—E. **Hildt**: The hydrolysis of the polysaccharides. Details of further experiments on the use of a mixture of sulphuric acid and sodium benzenesulphonate as a catalyst for the hydrolysis of the sugars. Glucose and galactose retain their rotatory and reducing powers unchanged under the action of this catalyst; non-lævulosic sugars, such as lactose and maltose, are

not hydrolysed at the ordinary temperature; whilst with saccharose and raffinose the lævulose is completely split off after sufficient time at the ordinary temperature or after one hour at 98° C.—L. **Cayeux**: The secondary quartz and the rhombohedral quartz in the iron minerals of the Longwy-Briey basin.—R. **Abrard**: The existence of the Aalenian stage in the massif of Zerhoun and at Djebel Tselfat (Western Morocco).—P. **Russo**: The alluvial terraces of Oum er Rbia (Western Morocco).—L. **Daniel**: Antagonistic reactions and the *rôle* of the pad in grafted plants.—A. **Guilliermond**: The structure of the plant-cell. Reply to a recent communication of M. Dangeard.—M. **Dangeard**: Reply to the preceding note.—E. **Licent**: The use of mixtures of formal and chromium compounds as fixing agents. Three formulæ are given for fixing reagents containing formal, chromic acid, and acetic acid in different proportions. Although the use in the same liquid of a powerful oxidising agent and a reducing substance would appear to be irrational, long experience has shown that such mixtures give excellent results.—E. **Roubaud**: The use of trioxymethylene in powder for the destruction of the larvæ of mosquitoes. Trioxymethylene exerts a specific toxic action on these larvæ, and has advantages over petroleum and other reagents in use. Detailed instructions for the best application of the trioxymethylene are given.—J. **Nageotte**: The toxicity of certain dead heterogeneous grafts.—A. **Goris**: The chemical composition of the tubercle bacillus. A new substance has been obtained from tubercle bacilli by extraction with chloroform and subsequent purification by precipitation from chloroform solution with ether, the fats remaining in solution in the ether and the new substance, named hyalinol, being precipitated. Seven grams were obtained from 1500 grams of the bacilli. An analysis and some reactions of the hyalinol are given.—R. **Duclaux**: The formation of asporogenic races of *Bacillus anthracis*. The attenuation of its virulence.—MM. A. **Trillat** and **Mallein**: Experiments on the transmission of an infectious disease in animals by the intermediary of air. Influence of the temperature.—MM. A. **Mayer, Guieysse, Plantefol**, and **Fauré-Fremiet**: Pulmonary lesions determined by blistering compounds. Studies on the pulmonary lesions caused by the inhalation of vaporised or pulverised dichloroethyl sulphide on the dog, rabbit, and guinea-pig.

Medical Research.

"A TEACHING hospital will not be content solely with making the best possible provision for the treatment of injury and disease and for imparting knowledge; it will recognise as one of its most important functions also the increase of knowledge.

"The problems of disease presented by living patients are the most difficult and complex in the whole range of the physical and natural sciences. Much light can be shed on them by investigations conducted in physiological, chemical, pathological, pharmacological, and bacteriological laboratories, especially by experimentation on animals; but it is increasingly clear that the scientific study of many of these problems can be undertaken with the greatest advantage in well-equipped, special laboratories connected with the hospital clinics and in charge of investigators trained in chemical, physical, and biological methods, with convenient access to the material for study and in close touch with the clinicians.

"The familiar analytical and statistical study of cases of disease, based on simple clinical observations, and first extensively and fruitfully applied by the great French clinicians of the early part of the last century, has been of immense service to medicine, and will continue to be of service. A good clinical observation has precisely the same scientific value as a fact demonstrated in the laboratory, and, even if more difficult of interpretation, is often the safer guide for the action of the physician.

"It is, however, from the special clinical laboratories that we may reasonably hope for a more penetrating insight into the causes and nature of many diseases, an insight which perhaps may arm physicians with a saving power of prevention and treatment of some of the organic diseases of advancing life comparable to the inestimable gifts of bacteriological laboratories to the prevention and treatment of infectious diseases. We must welcome the establishment of such laboratories and the new directions which they are giving to medical research. When the purposes of such laboratories are made clear, their foundation and support should make an especially strong appeal to public and private philanthropy."

I have quoted these remarks made some thirteen years ago by the distinguished leader of American medicine, Prof. William H. Welch, of the Johns Hopkins University, because they express so precisely the motive and the object of the reforms to be effected at the University College Hospital Medical School with the help of the Rockefeller gift. Dr. Welch spoke not only with deep insight and eloquence, but also with the experience he had gained as the Father of the Johns Hopkins Hospital and its famous Medical School.

The aim of the reforms of medical education that were introduced at the Johns Hopkins University in 1893 was primarily to educate the medical student rather than merely to prepare him for examinations. In other words, every encouragement was given him to learn by personal observation and experiment and to rely upon his own judgment; and he was provided with every facility in the way of properly equipped laboratories and ample material to carry out this scheme of work. Above all, he was given the time, undisturbed by multitudes of didactic classes, in which to cultivate his powers of observation and acquire knowledge by his own efforts. In other words, the ideal was to make every student and member of the staff devote himself to original research and the advancement of knowledge. How fruitful such a method can become we know from the history of our schools of physiology. The influence of the great reforms introduced at University College by Prof. Sharpey eighty years ago was carried to Cambridge by Sir Michael Foster, to Oxford by Sir J. Burdon Sanderson, and to the Johns Hopkins University by Prof. Newell Martin; and the result of these practical methods of studying physiology has been to convert almost every department of that subject into an institute of research and a perennial source of new knowledge.

The contrast presented by departments of anatomy in the English-speaking world, before 1893 in America, but even now in this country, is profound. The remarkable activity of physiology has been one of the contributory causes; and the very circumstance that Sharpey, the reformer of physiological education, was primarily a professor of anatomy was one of the factors in sterilising the spirit of adventure in his own subject. This paradoxical result was due to the fact that as a professor of anatomy and physiology Sharpey was

at liberty to take from the former subject the more vital and interesting parts with which to render attractive his own particular hobby, practical physiology. When his disciples carried the new physiological gospel to Cambridge and Oxford (thence to English-speaking schools the world over), histology and embryology were regarded as part of the work of the department of physiology. This could not have happened if anatomy during the last half-century had had any men like Sharpey, Foster, Burdon Sanderson, or Gaskell to claim their rights and obtain the necessary laboratories and equipment for real research in anatomy. Instead of this, while most of the schools of anatomy fell into a condition of inertia, the gospel taught in the one active and dominant school was the complete repression of the scientific imagination and the crushing of all research that was not a mere record of facts. Franklin Mall was able to do what he did in America because he was not subject to this paralysing influence which was crippling British anatomy.

It is necessary clearly to appreciate these historical circumstances in order to understand the present contrast between the attitude towards research in anatomy in American and British schools. In many of our departments no attempt whatever is made to add to knowledge; in fact, in certain of them there is not merely apathy, but even active opposition to original investigation. But, for the historical reasons I have mentioned, there is no adequate provision in any anatomical department in this country of the means for carrying on research, even when the staff and students are anxious to do so. Those anatomists who, in spite of these obstacles, have been keen enough not to be altogether discouraged by them have in many cases done excellent research, but only to find, in not a few instances, that their zeal was regarded as an obstacle to their professional advancement.

Now that this unfortunate and not very creditable chapter in British anatomy is coming to a close, it is important to get a clear idea of the aims of such an Institute of Anatomy as the Rockefeller Foundation's gift will enable us to build up in London.

The chief purpose of the new building will be to provide ample room and equipment to permit the staff, graduate students, and even undergraduates, to investigate any aspect of the problems of man's structure and development. There will be dissecting-rooms and museums for the study of macroscopic structure, and laboratories and museums for the investigation of the manifold problems of anthropology and man's evolution; but there will also be laboratories for the practical study of embryology, histology, and neurology, both human and comparative, and every necessary kind of equipment for work in any of these subjects. Proper provision is to be made for research in radiography, with special reference to the light it throws upon the structure and functions of the living body and its development. In other words, the new institute is intended to provide accommodation and equipment for research in every aspect of anatomy and anthropology; and the close association which is to be established with the departments of physiology and vertebrate anatomy and with the hospital will help to widen the outlook of investigators in anatomy and give them a clearer vision. Special importance is attached to this integrating aspect of our scheme of work, because it is proposed to create in the institute a department for the experimental study of the factors that influence growth and development and the causation of anomalies of structure and pathological monstrosities. Research in experimental embryology has been one of the most fruitful and significant fields of work in American anatomy departments within recent years. It is difficult to exaggerate the importance of the work carried on at the Carnegie Institute of Embryology by such men as Drs. Streeter and Lewis and their collaborators, by Dr. Ross Harrison at Yale, and by Dr. Stockard at Cornell Medical School, to mention only a few out of many.

In addition to these fields of investigation, many of the schools of anatomy in America carry on experiments in genetics, not so much for the purpose of studying Mendelism as for correlating the results of breeding experiments with other branches of work in anatomy and experimental embryology.

To carry out a programme of this sort it is our aim to have a staff numerous enough to give every member at least half his time free from teaching to devote to research; for a teacher who is not actually engaged in investigation is merely a retailer of second-hand goods.

At a time when this serious attempt is being made to provide proper facilities for carrying on research in anatomy, it is particularly gratifying to know that the University of Cambridge has appointed to its chair of anatomy the most learned British exponent of the technique of

anatomy and embryology. By his extensive and exact knowledge of anatomy and his technical skill, no less than by his personality and sound judgment, Prof. J. T. Wilson will exert a great influence in the encouragement of anatomical research in this country. His appointment to Cambridge inspires the confidence that the dark days of British anatomy are numbered.

G. ELLIOT SMITH.

Intellectual Stock-taking.

(1) *Science and Theology: Their Common Aims and Methods.* By F. W. Westaway. Pp. xiii+346. (London: Blackie and Son, Ltd., 1920.) Price 15*s.* net.

(2) *Recent Developments in European Thought.* Essays arranged and edited by F. S. Marvin. (The Unity Series.) Pp. 306. (London: Humphrey Milford; Oxford University Press, 1920.) Price 12*s.* 6*d.* net.

THERE seems to be a general disposition at the present time to take stock of the achievements of the human race in the generation which lived before the great cataclysm of the world-war. We feel, as mankind felt a hundred years ago after the great upheaval of the French Revolution and the succeeding Napoleonic struggle, that we are at the beginning of a new age. If we are to be effective in reconstructing and directing the new life of humanity, we must know the nature and extent of the forces in hand so far as they are under our control. The two books before us attempt this task in a very different manner. The first is the effort of a single worker to gather up and present, in a compact form and without bias, the definite results of recent scientific, religious, and philosophical research, and where they are conflicting or antithetical to state the case for each. The second book is the joint production of several workers, under the leadership of the author of "A Century of Hope," to express the characteristic features of the philosophy, religion, science, art, and history of the last half century, or more precisely of the period which begins with the Franco-German War of 1870 and ends with the outbreak of the great war in 1914.

(1) Mr. Westaway's work is primarily addressed to students of theology, and intended to aid them in finding a philosophic basis for their science. Before they can have this philosophic basis, however, they must, he thinks, master the main principles of mathematics, of science, and of scientific method. If, the student is told, he resorts to metaphysical arguments concerning the infinite before he has made himself acquainted with the nature of infinity in mathematics, he is violating the first principles of common sense. The same is true of physics, biology, and psychology. The student, we are afraid, will think it a hard saying, but then here is Mr. Westaway's epitome of the bases of all knowledge offered to him in tabloid form, compact and neat as in a medicine chest. Every theory that is held by anyone of authority in the sciences and philosophies, or which can be held, is set forth in abstract terms, and each summary of results is supported by a formidable list of books of reference. The theological student is left without excuse.

(2) A very different tone pervades the book edited by Mr. Marvin, for in this the personality of each of the twelve writers is given full expression. It makes the diversity more interesting than the unity. Perhaps the most telling contrast is between the positivistic tone of the general survey with which Mr. Marvin introduces the course, and the idealistic exuberance with which Miss Melian Stawell closes it. But surely the oddest contribution to the volume is Prof. Taylor's estimate of the philosophy of the last half century. It begins with a mystifying line of asterisks, and ends with a "note." The note is appended as an "apology" for omitting Bergson, or, rather, for refusing to regard that philosopher as other than a transient and spent force. The reason given is that his earliest work in its opening chapter contains "a couple of elementary blunders," and on these the whole of his philosophy is based. The note is certainly necessary, because the other essays in the volume might easily lead the reader to imagine that the period had been dominated by the philosophy of Bergson.

The meed of honour in philosophy is awarded by Prof. Taylor to Mr. Bertrand Russell, mainly on account of his joint work with Prof. Whitehead in "Mathematica Principia." He thus agrees with Mr. Westaway in holding the mathematical theory of infinity to be the basis on which philosophy must build. There can be no doubt that if the award is to be decided in the manner of the Greeks after the battle of Salamis, Mr. Russell must be acclaimed *facile princeps*, for there is no living philosopher in regard to whom such striking unanimity prevails. No one agrees with him, but everyone is anxious to set forth his reasons for disagreeing. Prof. Taylor is no exception. He looks in vain for any recognition by Mr. Russell of what he regards as the one vital and absolute necessity of philosophy, the attainment of knowledge about the soul and God. For this he refers us to the two eminent Italian

professors, Varisco and Aliotta, and omits any reference to their more celebrated contemporaries, Croce and Gentile. His prayer is "for a Neo-Thomist who is also a really qualified mathematician."

All the essays in the volume are interesting. Principal Jevons writes of religion from the point of view of folk-lore study; Mr. Gooch has given an admirable review of the history of historical research, the science which Croce names "storiografia"; while Prof. Bragg treats of "atomic theories," but is only able to indicate in a note the new interest aroused by the work of Einstein. Of this it is too early to take stock. H. W. C.

Petroleum Geology.

Geology of the Mid-Continent Oilfields. Kansas, Oklahoma, and North Texas. By Dr. T. O. Bosworth. Pp. xv+314. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1920.) Price 3 dollars.

IN this the latest contribution to the geology of the great Mid-Continent oilfields, Dr. Bosworth has contented himself with summarising the results of most of the recent work published by American geologists in the Bulletins of the United States Geological Survey, and in those of the Oklahoma and Texas Surveys in particular. His aim throughout has been to present the facts, leaving deductions to the intelligence of the reader, since, although he sets out with the intention of reviewing those facts, he does not succeed in attaining this end, for his final chapter, devoted to general conclusions, mainly deductive, occupies only a little more than five pages out of a total of 282 of text, and cannot be regarded as more than a somewhat hurried and non-committal postscript to the preceding sections of the book.

To any keen student of petroleum geology the announcement of a new publication dealing with one of the world's greatest oilfields is to be regarded with a certain degree of anticipation, partly with reference to possible new theories of oil accumulation and development, and partly (in this case) from a curious desire to see how far the teachings of the British geological school may be affirmed or modified by association in their own country with American oil technologists. This dual anticipation, however, is doomed to disappointment, because there is certainly nothing strikingly new in Dr. Bosworth's book, and one further perceives in the work a strong under-current of bias to prevalent American opinion.

It was to be hoped, for example, that new light would be thrown on the structure of the North and Central Texas fields, which are of such recent development and importance; but, beyond a brief description of the local "closed dome," "nose," and "terrace" structures originally described by Dorsey Hagar in his paper before the American Institute of Mining Engineers (1917), little information is forthcoming.

Another point on which more information is desirable is the possibility of the future development of the fields to the west. The general west-ward dip of the Palæozoic rocks tends to shift the oil horizons of the Pennsylvanian beds deeper and deeper in that direction, and further prospecting must inevitably lead to deeper drilling, assuming the structure to remain uniform. But it is by no means certain that such is the case, and on this point the author is unable to enlighten us. He suggests certain possibilities in regard to locating oil in the underlying Mississippian and in the over-lying Permian "Red" beds; but in the former case the great depth to which borings must necessarily penetrate will tend to limit operations, whilst in the latter the oil occurrences are probably extremely localised, the conditions obtaining in the Healdton (Permian) field, which he quotes at some length, being the exception rather than the rule. It is only fair to add, however, that the short-sighted policy of many of the oil companies in prohibiting the publication of the results of detailed surveys prevents many workers from doing full justice to their research, and science, in consequence, must suffer accordingly.

It is interesting to note that in his conclusions the author regards the "vegetable" hypothesis as accounting for the origin of the hydrocarbons, and he further recognises White's laws of progressive devolatilisation as applicable to the Mid-Continent fields, an opinion which is in accordance with American views.

For the rest, the book certainly contains some useful features, the stratigraphy of the oilfields and the relations of oil accumulation to structure in most of the important fields being treated very concisely. The chemical side is by no means neglected, and the general characteristics of the Mid-Continental oil and natural gas, and the production of gasoline from that gas, are dealt with in some detail. Maps, plans, and photographs of the fields are included, together with a bibliography of the more important works relative to the area. The volume will probably make its strongest appeal to those who wish to gain a broad idea of the geology of the oilfields without having recourse to survey and other technical publications.

H. B. MILNER.

Fuel Problems.

Fuel Production and Utilisation. By Dr. H. S. Taylor. (Industrial Chemistry Series.) Pp. xiv + 297. (London: Baillière, Tindall, and Cox, 1920.) Price 10s. 6d. net.

THIS volume is intended more especially as a post-graduate book which shall "supplement academic training with the broad facts of fuel production and utilisation." The main sources from which the author has drawn his material are the valuable bulletins issued by the United States Geological Survey and the Bureau of Mines, supplemented by other American and Canadian sources of information. Everyone familiar with fuel problems realises the great value of these publications, and although many of the author's quotations from these and his other sources are lengthy, his judicious selection of material has enabled him to compile a volume which cannot fail to be of value to a much wider circle than post-graduate students.

A great change in the fuel problem has followed from the enormous rise in the price of coal, and it is difficult to see what the far-reaching ultimate effect will be. Certain it is that man will be driven to consider the utilisation of much material which has hitherto received but little attention, and to give closer attention to using the last heat unit possible in every ton of coal. While coal was cheap economists preached to deaf ears; economic necessity will produce effects which years of preaching failed to accomplish. Dr. Taylor's book should go a long way to help those who are prepared to take the serious view which the situation demands of these problems, and it is of value not only as recording what has been done in the near past, but also as indicating possibilities in fuel utilisation in many directions.

One of the features of the book is the broad outlook of the author on many of the problems which, whilst at present of very minor importance, bear evidence of becoming of considerable practical importance with the great alteration in conditions in the fuel situation. The utilisation of the minor fuels—peat wood, coke for industrial purposes, and pulverised coal—together with the many problems associated with the low-temperature distillation schemes, are more adequately dealt with by Dr. Taylor than by most writers of general books on fuel, the considerable space devoted to these problems being amply justified by their potential importance.

From the scientific point of view the "synthetic" fuels are of considerable interest. In the future some may become of great importance. The merits of alcohol as a fuel are now very widely recognised, and the author gives an excellent account of this question. Closely connected—indeed, part of the problem—is acetylene as fuel, either directly, for small motor vehicles have been driven by this gas, or more specifically as a possible source of alcohol. Several processes for the conversion are referred to, the steps usually involving the formation of aldehyde by absorption in acids, generally in the presence of mercury salts, and the conversion of the aldehyde into alcohol by reduction by Sabatier's method with hydrogen in the presence of nickel as a catalyst.

Of a similar character is the production of hexahydrobenzene (hexamethylene) by the hydrogenation of benzene. The author points out the advantages of such a fuel of constant composition and properties, but he does not refer to the one great disadvantage of this compound, namely, its high freezing point (6·4° C.). He refers to it as suitable for aeroplanes, but this high freezing point obviously entails serious difficulties. In admixture the claim for homogeneous composition is gone, and even alone it is difficult to see what advantages it possesses over benzene, which has approximately the same freezing point, or even over commercial "benzol," which freezes below 0° C. and has no greatly varying degree of volatility.

J. S. S. B.

Hurter and Driffield.

A Memorial Volume containing an Account of the Photographic Researches of Ferdinand Hurter and Vero C. Driffield: Being a Reprint of their Published Papers, together with a History of their Early Work and a Bibliography of Later Work on the Same Subject. Edited by W. B. Ferguson. Pp. xii + 374. (London: The Royal Photographic Society of Great Britain, n.d.) Price 25s.

DR. HURTER died twenty-two years ago, and Mr. Driffield afterwards did little or nothing more in connection with their joint labours than complete and publish the work that was almost finished. It is possible now, therefore, to regard their work as a whole, and to see something of the relationship that it bears to the general progress of photography from the scientific point of view.

Hurter and Driffield did two very considerable things. They devised the method of drawing what they called, and what is now universally known as, the "characteristic curve" of a developable sensitive surface. This may at first appear a very easy thing to do, but it is often the things that are easy to do which are the most difficult to get at and of

the greatest fundamental importance. With the curve are, of course, included the units that it involves and the facts that it represents. As to its advantages, it is enough to say that it was at once adopted wherever photography was regarded as a science, and no better method of expression has since been suggested.

Their second notable achievement was that they promulgated certain conclusions to which they had come with an energy and assurance that stand unique in connection with this, if not with all scientific subjects. Their statements in their communication of 1890 with regard to some of the opinions and experiences of others as interested in the subject as they were, were put in such vigorous language that they amounted to challenges. Of course, this led to discussion and to further work; and discussion breeds discussion, and work breeds work. Dr. Hurter and Mr. Driffield either separately or jointly were always ready to take any pains, by reading papers, often travelling long distances to do so, by writing articles, or by personal correspondence, to make clear and to uphold their views. They thus administered a powerful stimulant to scientific photography.

It is of very secondary interest what these views were, because the whole subject has received since then more attention than any two persons could possibly devote to it; and, indeed, Hurter and Driffield themselves, in their last important communication on "The Latent Image and its Development," demonstrate by further experiments the necessity of largely, if not radically, modifying the statements to which so much exception had been taken.

It must not be supposed that Hurter and Driffield set out with the intention of doing the two things that we have endeavoured to describe. To quote their own words: "Our object was to discover a method of speed determination, and it was not, as the [photographic] public seemed to infer, to deal finally and exhaustively with the subject of development. This subject was purely incidental. . . ." As everyone knows, they did devise a method for the estimation of sensitiveness, and, as might be expected from such capable men, a method wholly different from any other, but, like all methods, it has its advantages and its disadvantages. The sensitiveness of a plate is not definite except under definite conditions, and in practical work the conditions are not uniform.

It is but a short step from the courteous and ever kindly Hurter and Driffield to the memorial volume before us, because Mr. Ferguson has done his work well and with full sympathy. The volume begins with Mr. Ferguson's recent lecture on their early work, which is followed by a review of Dr. Hurter's mathematical work by Dr. H. Stanley Allen, and by the patent specifications of the early actinometer and the actinograph. Then come reprints of all their important communications to societies and journals. Mr. Ferguson has certainly not erred in the direction of making too exclusive a selection, though he tells us that there are many other publications of theirs, chiefly polemical letters to the photographic Press, which, if reproduced, would have filled two more volumes. After this there are a bibliography of 717 items, extending from 1881 (Hurter's actinometer patent) and 1888 (the actinograph patent) to 1918, and name and subject indexes. If there should exist anyone interested in scientific photography who is so saturated with the work of Hurter and Driffield that the reprints do not appeal to him, even he cannot fail to find the bibliography and indexes of considerable use.

C. J.

Our Bookshelf.

Bygone Beliefs: Being a Series of Excursions in the Byways of Thought. By H. Stanley Redgrove. Pp. xvi+205+32 plates. (London: William Rider and Son, Ltd., 1920.) Price 10*s*. 6*d*. net.

THIS series of fragmentary discussions extends over a vast area: Pythagoras and his philosophy, medicine and magic, bird superstitions, powder of sympathy, talismans, ceremonial magic, architectural symbolism, the Philosopher's Stone, the phallic element in alchemical doctrine, Roger Bacon, and the Cambridge Platonists. It is inevitable that a discussion of such varied subjects in a limited space is not likely to be fruitful, nor will the author's interpretations command universal acceptance. Thus we are told that "the alchemists regarded the Philosopher's Stone and the transmutation of the base metals into gold as the consummation of the proof of the doctrines of mystical theology as applied to chemical phenomena," though some were influenced by more material objects. The premises from which they started were "the truth of mystical philosophy, which asserts that the objects of Nature are symbols of spiritual verities. There is, I think, abundant evidence to show that alchemy was a more or less deliberate attempt to apply, according to the principles of analogy, the doctrines of religious mysticism to chemical and physical phenomena." Of course, it is generally admitted that the idea of transmutation had a philosophical basis such as it was, and that alchemy to some extent unified and focussed chemical effort, but it was, to use Liebig's words, "never at any time anything different from chemistry."

While it is difficult to accept the author's transcendental interpretations of these and kindred phenomena, he has collected much curious learning, for which he supplies adequate references,

and he gives us a number of curious illustrations, one of which, however, may judiciously have been omitted in a book which claims to be popular.

The Propagation of Electric Currents in Telephone and Telegraph Conductors. By Prof. J. A. Fleming. Third edition, revised and extended. Pp. xiv+370. (London: Constable and Co., Ltd., 1919.) Price 21s. net.

IN preparing a new edition of his well-known study of the propagation of telegraph and telephone currents, Prof. Fleming has taken the opportunity of bringing it in line with both the latest theoretical and the latest practical work in this field. The subject presents a very fine example of mathematical investigation leading to results of far-reaching practical utility, and the author conducts his reader along a logically continuous path from the point where he introduces him in the first chapter to hyperbolic functions of complex angles, to the page near the end where he pauses to show him a picture of a telephone cable with loading coils being laid across the Channel. Telegraph and telephone engineers owe a great debt of gratitude to Prof. Fleming for the way he has, at first in his lectures and then in the volume now before us, brought together so much valuable work in this complicated subject, to which he himself has been no mean contributor. Perhaps the most valuable feature of the treatment is the way in which he has simplified, so far as possible, the mathematical results of the original investigators, while at the same time facilitating the building of the bridge from the other end by providing the material to extend the student's mathematical resources in the required direction.

Half-past Twelve: Dinner Hour Studies for the Odd Half-Hours. By George W. Gough. Pp. vi+77. (London: Sells, Ltd., n.d.) Price 1s.

THERE is abundant evidence that much of the present-day industrial unrest arises from the ready acceptance of fallacious economic ideas by many of those engaged in industry. The need for sound teaching in the first principles of economics of a character within the ready understanding of working men and women, and of all who help to form public opinion, is acute, and Mr. Gough has rendered a valuable service in helping to satisfy this need.

This inexpensive little book is an attempt to correct wrong economic ideas and a limited perspective by providing a series of talks on familiar economic topics such as production, capital, profits, wages, the mechanism of exchange, and the principles of taxation. The author deals with these in a brief but extremely lucid manner, and his conclusions, while significantly orthodox, are arrived at without bias or prejudice. His illustrations are most apt, and will effectively secure the interest of his readers. It is to be hoped that this publication will be widely read not only by industrial workers and students, but also by the public generally. A. P. M. F.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Separation of the Isotopes of Chlorine.

PROF. SODDY (June 24) and Mr. Core (July 8) have in their comments on my letter in NATURE of June 17 raised several points of interest. The former asks that all the assumptions from which the equation

$$[Cl'_2][Cl_2]=[ClCl']^2$$

was deduced may be given. The assumptions are:

(1) The differences between the vapour pressures of the three varieties of chlorine are negligibly small.

(2) The vapours are almost perfect gases.

(3) The three varieties of gaseous chlorine are separable by semi-permeable membranes or other means, or the equivalent assumption that the thermodynamic potential of a mixture of the three varieties is the sum of the thermodynamic potentials of the constituents.

(4) The work required to convert reversibly 1 mol. of solid Cl'_2 and 1 mol. of solid Cl_2 into 2 mols. of solid ClCl' is negligible.

The three last assumptions lead us to the formula

$$0=\log_e K+\log_e\frac{\{ClCl'\}^2}{\{Cl_2\}\{Cl'_2\}}$$

where the bracket { } indicates concentration of saturated vapour. Whence with the aid of assumption (1) we deduce that $K=1$.

Assumption (4) follows from Nernst's heat theorem if it be postulated that the energy of the change considered is almost zero. It would appear, therefore, that if isotopes are inseparable by processes similar to that described in my first letter, one of the assumptions made is not valid.

Prof. Soddy asks whether there is any step in my argument to prevent its being applied to prove the possibility of the separation of arbitrarily selected atoms from a group of completely identical molecules by chemical means; for, if there is not, then it follows, as a *reductio ad absurdum*, that the equilibrium equation

$$[Cl'_2][Cl_2]=[ClCl']^2$$

is wrong, and it is unnecessary to test its validity by experiment. Concerning this query I am in doubt whether it would be generally admitted that assumption (3) could be made in such a case as that contemplated by Prof. Soddy, and therefore I think it is desirable that the question of the validity of the equation should be submitted to the test of experiment—so far as it is possible to do this.

Mr. Core assumes that the isotopes of chlorine are inseparable by chemical means, but does not agree with my conclusion that if such is the case Nernst's heat theorem will be difficult to defend. He admits that at finite temperatures the difference in entropies of the solid reactants and resultants is $R\log_e 4$, but he argues that it may become zero at zero temperature owing to the effects of the differences in properties of the three solids being more pronounced at exceedingly low temperatures. But even if it be admitted that in the case of chlorine the difference between the entropies of the reactants and resultants can be nothing at zero temperature and $R\log_e 4$ at finite temperatures, it has still to be explained how the same rise in the difference of entropies from zero to the constant value $R\log_e 4$ could occur for a change of the same type in the case

of another element which exists in the form of two isotopes differing much less in their atomic weights than those of chlorine. Furthermore, if we put $A=f(t)$, and if $f(t)$ can be expanded in the analytical series,

$$f(o)+t.f'(o)+\frac{t^2}{|2}.f''(o)+, \text{etc.},$$

and $f'(o)$ is zero as Nernst assumes, then it must be explained how the series

$$f(o)+\frac{t^2}{|2}f''(o)+, \text{etc.},$$

can become almost equal to $t.R\log_e 4$ between wide limits of temperature.

In fact, if the isotopes are inseparable by chemical means, I think that the most natural conclusion to draw is that the difference in the entropies of the reactants and resultants of a chemical change taking place at zero temperature is a finite quantity which depends on the type of the change, and also, of course, on the number of molecules transformed.

Jesus College, Oxford. D. L. CHAPMAN.

Anti-Gas Fans.

OWING to my absence from home I did not see Prof. Allmand's letter in NATURE of June 10 on my indictment of the War Office until too late to reply to it last week, but I hope you will now allow me to put before your readers a few of the points he has missed.

First, may I repeat that I had no personal interest in the number of fans sent out, since I neither asked for nor would accept payment or reward *of any kind or description* for their use during the war. I attributed the suffering and loss of life, which I deplore and Prof. Allmand denies, even more to the lack of training, and consequent ignorance of what the fans could do, than to their scarcity.

From this letter I gather that his own knowledge concerning them is of the slightest. He seems never to have heard of the clearing of trenches with them, the purpose to which they were principally put; but he allows that they were "found useful" for clearing shelters and dug-outs that would otherwise have remained dangerous for "hours, or even days," after a gas attack. We have only to picture our men, after hours of hard fighting, perhaps wounded or already gassed, compelled to remain in the open, whatever the weather, with the remains of gas still there, to realise the vital importance of clearing every space, dug-out, and shelter the moment it was possible. Yet for a whole year (May, 1915, to May, 1916) the use of the fans with which it could always have been done in a few minutes was held up by the wilful obstruction of War Office officials. It must be remembered, too, that at the beginning of that year the respirators were still quite crude and untrustworthy, and that even by the end of it they were very far from perfect. Is it too much to say, then, that "much suffering and loss of life could have been avoided" had the fans been accepted, and the troops properly trained to use them, nine months earlier, as they could so well have been? On this point Prof. Allmand is silent.

He says that, later, fires were found to be as efficacious as, and less fatiguing than, fans. They were not as efficacious, but they were certainly less fatiguing, as I have said, when the materials were ready to hand; and it was perfectly right to use them when practicable. But each time a space was cleared by fire, fresh *dry* wood and paper were required. Now it is common knowledge that there were wide areas which, over long periods, were so wet that dry wood for even one clearing would have been hard to find, let alone many. Is it an exaggeration to say that "much suffering and loss of life could have been avoided" if those responsible had remembered this, and had provided not only plenty of fans for every area, but also men trained to use them? On this point also Prof. Allmand is silent.

"Working an Ayrton fan, *even in the most approved fashion*"—my italics—he says, ". . . is a tiring task." Prof. Allmand will, I am sure, be surprised to learn that there are at least three approved fashions, and that the efficiency of the fans depends almost more on the ability of the officer in charge to choose the right method for the particular space, and to place and move his men properly, than on the skill of the wielders; moreover, the approved methods are not less fatiguing than the wrong ones, only infinitely more efficient. This ignorance on the part of an authority on anti-gas methods is not unique; it is typical. Let me show how it arises.

As soon as the fans were accepted I warned the War Office that, if they were to be of any value, officers and men alike *must* have two or three days' practical training in their use; and, at the request of the Commander-in-Chief, my assistant went to France to show how the training should be carried out. At first, after he left, it may have been fairly well done; but in time those who had seen for themselves what the fans could do died or became scattered; and after that the training degenerated at best into an hour or two of exercise in the stroke for trench-clearing, and at worst into the mere exhibition and naming of a fan, while numbers of men never even saw one at all. Major Gillespie, D.S.O., who practically saved his battery by means of the fans, when a howitzer battery within a hundred yards of it was wiped out, wrote to the *Times* of May 4: "Even after the introduction of the fans in limited quantities, I never met an officer or man who had been properly instructed in their use." This ignorance, for which the War Office is responsible, extended from the highest to the lowest officials in the Anti-Gas Service. The only men who did not share it were those officers who were clever enough and interested enough to make out for themselves what could be done with the fans. Small wonder, then, that most officers regarded them simply as nuisances, and that some of the men treated them as fuel.

This same ignorance and want of imagination led to the idea that the fans were useless for dealing with mustard gas. In describing the saving of his battery Major Gillespie wrote: "The gas hung about for days afterwards, but by judicious flapping at frequent intervals we kept our quarters fairly free from it." This is the evidence of a "fighting soldier." It is odd that those other fighting soldiers quoted by Prof. Allmand should not have thought of this very simple way of ridding themselves of a vapour that came off slowly and took some time to reach a dangerous concentration.

Finally, is not Prof. Allmand in his last sentence confusing scientific methods with the methods of some scientific men? In directing attention to the dire effects of the unscientific methods of the War Office in connection with anti-gas fans, I was adding my quota to the efforts of those who are trying to "ensure the application of scientific methods to military problems." The fact that it was scientific men who were responsible for those unscientific methods is surely no reason for condoning them, but rather for censuring them the more severely.

HERTHA AYRTON.

41 Norfolk Square, W.2, June 22.

AT the risk of the accusation of shirking inquiry, I repeat that I have no intention of entering into a

controversy with Mrs. Ayrton. It will suffice to say that she is writing of things of which her knowledge is, naturally, second-hand, besides being clearly very inadequate. This is apparent in at least eight separate points in her letter, of which I will only refer to her mention of the successful use of the fans in what must obviously have been a *very* exceptional type of "mustard-gas" bombardment. I assure Mrs. Ayrton that she is mistaken if she imagines that she has in this matter any considerable body of support amongst those who knew the facts, from whatever point of view. I hope, in conclusion, that nothing I wrote has led Mrs. Ayrton to suppose that I regard her advocacy of her fans to be influenced by questions of "payment or reward." Nothing was further from my mind.

A. J. ALLMAND.

King's College, W.C.2, June 30.

PROF. ALLMAND, having read neither the specific charges I have made against the War Office nor the evidence, principally from official documents, with which I have sustained them, attempts to counter them with statements unsupported by evidence of any kind. He finds me ignorant, for instance, on eight points, of which the only one he names is obviously no matter either of my knowledge or ignorance, since it refers simply to a quotation from the letter of a very able and gallant "fighting soldier." Had he read the article he criticises he would have seen the whole quotation.

I am ready to sustain those charges, and to produce the evidence before any proper tribunal. I repeat them.

I accuse the War Office of having caused great loss of life and much avoidable suffering by:

(1) Having refused for a whole year to make use of anti-gas fans, which they were yet compelled finally to adopt owing to their proved efficacy.

(2) Never having set up an efficient organisation for training officers and men in their use, although I had warned them that this was indispensable.

(3) Having thus deprived the troops of the knowledge requisite for understanding what could be done with the fans, and having thereby induced the idea that they were useless.

(4) Having trusted entirely to fires for clearing dug-outs of gas, regardless of the fact that in many places dry wood and paper were often unobtainable.

(5) Ranking sandbags and ground-sheets as of equal efficacy with fans for clearing gas.

(6) Sending out an inadequate supply.

The scientific men implicated in these grave charges have not even made the plain statement with regard to them that the Editor of NATURE considered so desirable, much less produced any evidence in refutation of them.

HERTHA AYRTON.

July 11.

THE continuance of this correspondence in our columns would not, we think, serve any useful purpose. In a note in NATURE of May 13 it was pointed out that Mrs. Ayrton's indictment of the War Office was "not against the military element, but rather against the experts who were associated with the Gas Service." It is easy to understand the reluctance of these officers to express their views upon anti-gas fans, even if they were free to do so; and though Mrs. Ayrton is anxious to have all the facts judged by a tribunal appointed for that purpose, we must confess that the likelihood of a scientific body constituting such a tribunal is very remote. The inquiry is one that the Conjoint Board of Scientific Societies could take up appropriately, but no satisfactory conclusion could be reached without examining a number of witnesses, and the resources and powers of the Board are scarcely sufficient for such action. The only practicable course, therefore, would seem to be for the War Office to appoint a Committee to investigate Mrs. Ayrton's charges, and in the interests of scientific truth and efficiency we hope this will be done.—ED. NATURE.

The Stretching of Rubber in Free Balloons.

IN NATURE of June 10, p. 454, in connection with the attainment of high levels of the atmosphere by sounding- or pilot-balloons, Mr. W. H. Dines considers that such balloons would burst before reaching great heights, as the rubber of which these balloons are made would be stretched eightfold linearly, and he remarks that he does not think that any rubber will stand this treatment.

Properly vulcanised soft rubber will, however, stretch to more than ten times its original length if in the form of a ring-shaped test-piece. Moreover, the load increases more rapidly than the elongation at the later stages. The remarkable tensile properties of soft rubber are not always sufficiently recognised. The breaking strain of a properly vulcanised sample should be not less than 1500 grams per sq. mm. cross-sectional area of the original test-piece. Allowing for the stretching, which would reduce the cross-sectional area to one-tenth, the breaking strain would be 15,000 grams per sq. mm. cross-sectional area of the sample when fully elongated, or nearly 10 tons per sq. in. It would not, however, be safe to rely on these figures, as the rubber of the balloon would tear at the neck where it is tied together before the bursting pressure was reached. Mr. Dines has also failed to take into consideration the fact that part of the hydrogen would be lost by diffusion during the ascent of the balloon, which would reduce the pressure of the contained gas.

HENRY P. STEVENS.

15 Borough High Street, London Bridge, S.E.1, June 29.

WITH reference to Mr. Stevens's interesting statements about the stretching of rubber, I think he has overlooked the fact that in a balloon the rubber is stretched simultaneously in both directions, whereas he refers apparently to one direction only.

I have cut a strip half an inch wide from a balloon used at Benson; it stretched sevenfold before breaking, but when extended sixfold its width was reduced from 0·50 in. to 0·22 in., instead of being extended to 3·00 in., as would be the case in actual use. Its unstretched thickness was 0·013 in., its thickness at breaking greater than 0·004 in., but when extended sixfold each way its thickness would only be 0·00036 in.

The loss of hydrogen by diffusion or leakage is equivalent to not giving the balloon so large a free lift at starting, and would alone increase the height, but in practice it sometimes leads to the bursting height not being reached at all because the free lift has vanished before that point is reached. It has been found that within fairly wide limits the maximum height is only slightly dependent on the free lift at starting. But diffusion of the hydrogen outwards is accompanied by diffusion of air inwards, and this increases the specific gravity of the gas and lessens the height.

I did not mention the effect of the tension of the rubber on the pressure, and therefore on the specific gravity, of the enclosed gas. Taking Mr. Stevens's figure of a breaking strain of 15,000 grams per sq. mm. of unstretched section, this will raise the internal pressure by quite an appreciable amount, and thereby reduce the height at which the balloon bursts.

Benson.

W. H. DINES.

Note on the Habits of the Tachinid Fly, *Sphexapata (Miltogramma) conica.*

FABRE has given a graphic account of the patient watch of this parasitic cuckoo-fly at the mouth of the burrow of a species of Bembex, and of its cunning in seizing the moment when the "wasp" is half within the burrow to deposit its tiny egg, pregnant with disaster to the Bembex offspring, upon the body of the insect victim intended for the larder-nursery wherein the mother Bembex's hopes are laid. He does not, however, appear to have witnessed in the tragedy a phase that recently came under my notice, and that is possibly restricted to, or perhaps only easily observed, in cases where the foster-host carries its prey along the surface of the ground, or at best flies only just clear of the ground.

On the afternoon of June 22, when on one of the heaths in this neighbourhood, I caught sight of a black Fossor, *Tachytes unicolor*, carrying a paralysed grasshopper. I followed, hoping to secure a photograph of its operations at the burrow. Soon I discovered that I was not the only follower, for at a distance of about four inches there followed a small Tachinid fly, which Mr. J. E. Collin has kindly identified as *Sphexapata conica.* The fly followed the "wasp" with the utmost accuracy, maintaining its distance with a precision that suggested a rigid connection between the two insects; if the "wasp" flew, the fly flew; if the "wasp" crawled, or indeed took but a single step, the fly did exactly the same; and always keeping distance accurately. For more than fourteen yards—and there may have been many more before I came upon the scene—did the fly thus follow in the wake of the "wasp," until at length the burrow was reached. The "wasp" at once entered, leaving the grasshopper lying, belly upwards, at the burrow's mouth; but before the owner was out of sight the fly darted upon the grasshopper, without a moment's delay deposited an egg on its thorax, and flew off—into my net.

Fabre says nothing as to the distance at which the fly stations itself when keeping watch at the mouth of the burrow, nor of the interval between each individual when several "in a geometrical line" are awaiting the critical moment; but the constancy with which the fly kept station in the journey across the heath, and the precision with which every movement of the "wasp" was copied, suggested that at that particular distance a clearer visual image was secured than at any other. Be this as it may, the fact is worth consideration in discussing insect vision.

To this note I may appropriately add an observation made last year while watching an *Ammophila sabulosa* filling in its completely stocked burrow. On a stone close by there sat a small fly absolutely motionless, and apparently intently watching the proceedings. As soon as Ammophila had finished its work and flown off, the fly leapt from its perch, and at once began to scratch away the sand and small stones in an endeavour to get at the larvæ in the subterranean larder. Fortunately, Ammophila had packed its burrow too well, and the fly flew off defeated. This fly closely resembled *Sphexapata conica,* but may have been an allied species.

Sharp ("Camb. Nat. Hist.," vol. vii., p. 509) mentions the fact that Miltogramma follows Hymenoptera carrying prey. OSWALD H. LATTER.

Charterhouse, Godalming, July 4.

Temperature Variations at 10,000 ft.

A SERIES of 500 aeroplane observations in North-East France in 1918–19 throws some light on the problem of temperature variations in the upper air. The correlation coefficient between pressure and temperature at 10,000 ft., taking all the observations together, is 0·73. If the seasonal variations are allowed for by taking the deviations from Mr. W. H. Dines's smoothed monthly means, the coefficient is 0·69. The former value is higher, as the annual variations of temperature and pressure in the upper air are in the same phase. Both figures are rather lower than the value 0·77 for 3 km. obtained by Mr. Dines from balloon soundings, the observations being grouped in three-monthly periods. The value 0·69 implies that a proportion $\sqrt{1-0{\cdot}69^2}$, or 72 per cent., of the standard deviation is still unaccounted for. The partial correlation coefficient between the temperature and the southerly component of the wind velocity at 10,000 ft. (allowing for the pressure) is 0·44, so that the southerly component accounts for 10 per cent. of the temperature variations which are independent of the pressure, or 7 per cent. of the total variations. The effect of the west component of the wind velocity is practically negligible at all seasons.

There are strong grounds for believing that a large proportion of the temperature variations depends upon whether the air supply was drawn originally from the polar basin or the equatorial belt. This view is supported by the humidity observations which were made at the same time as those for temperature. For reasons set out in a paper which I hope to publish, the original source of the air supply is not very closely related to the wind velocity at the place of observation, both polar and equatorial currents frequently following curved paths. This factor of air supply operates in a very irregular manner, with the result that the correlation coefficients vary greatly from month to month. The coefficient connecting pressure and temperature at 10,000 ft. for the period January–February, 1919, based on fifty observations, is as low as 0·09. In the winter especially there are large fluctuations of the upper-air temperature, the changes occasionally exceeding 30° F. within forty-eight hours both at 10,000 ft. and 14,000 ft.

Mr. Dines gives a value 0·86 to the pressure-temperature correlation coefficient from 5 km. to 8 km., but this accounts for only half the temperature variations. C. K. M. DOUGLAS.

Meteorological Office, Air Ministry, W.C.2, July 8.

The Brent Valley Bird Sanctuary.

SUNDAY next, July 18, is the two hundredth anniversary of the birth of Gilbert White of Selborne, who did more than any other of our countrymen to create an interest in birds. The moment is therefore ripe for an appeal upon their behalf, and for suggesting how a fitting memorial to him may be established.

The work which the Selborne Society has done in the Brent Valley Bird Sanctuary, in the way of preserving birds and testing nesting-boxes for use elsewhere, is well known and has some considerable value. The owners of the freehold wish now to develop their estate, and if the money necessary to buy the property is not forthcoming the sanctuary will go.

Matters have been made as easy as possible for us, and we have been asked only 4500*l.* for twenty-two acres of building land which comes into the London postal district.

May I, as chairman of the Bird Sanctuary Committee, invite the help particularly of those who are fond of birds and of open spaces to save the wood? Those who have been immediately interested in the work have subscribed 300 guineas to start the fund. WILFRED MARK WEBB.

The Hermitage, Hanwell, W.7, July 10.

Researches on Growth of Plants.

By SIR JAGADIS CHUNDER BOSE, F.R.S.

I.—*The High Magnification Crescograph.*

INVESTIGATION on growth is a matter of much practical importance, since the world's food supply is intimately dependent upon vegetative growth. The movements of stems, leaves, and roots under the action of various forces, such as light, warmth, and gravity, are often due to minute variations in the rate of growth. The discovery of laws relating to the movement of growing organs thus depends on the accurate measurement of normal growth and its changes. The great difficulty of the investigation arises from the extraordinary slowness of growth, the average value of which per second may be taken as $\frac{1}{100000}$ in., or half the wave-length of sodium light. The "auxanometers" usually employed produce a magnification of about twenty times. Even here several hours must elapse before growth becomes perceptible, but during this long period the external conditions such as warmth and light would necessarily change, thus vitiating the results; moreover, autonomous variation of growth appears during lengthy periods. The elements of uncertainty can be removed only by reducing the period of experiment to a few minutes; but that would necessitate devising a method of very high magnification and the automatic record of the magnified rate of growth. I have been successful in this by my device of the High Magnification Crescograph, consisting of a system of two levers; the first magnifies a hundred times, and the second enlarges the first a hundredfold, the total magnification being 10,000 times. The various difficulties connected with the weight and friction at the bearing have been fully overcome.[1] The further difficulty in obtaining an accurate record of growth movement arising from friction of continuous contact of the writing point was removed by an oscillating device by which the smoked glass plate moves to and fro at regular intervals of time, say one second (Fig. 1). The record consists of a series of dots, the distance between successive dots representing magnified growth during a second (Fig. 2*a*).

The records may be taken on a stationary plate, first under normal, and then under changed, external conditions. The increase or diminution of space between successive dots in the two series demonstrates the stimulating or depressing nature of the changed condition (Fig. 2*d*); or the record may be taken on a plate moving at a uniform rate. In the curve thus obtained the ordinate represents growth-elongation, the abscissa the time. If a stimulating agent enhances the rate of growth, this fact is exhibited by a flexure in the curve upwards; a depressing agent, on the other hand, lessens the slope of the curve (Fig. 2*b*).

Precautions against Physical Disturbance.—The effect of vibration may be neutralised by placing india-rubber sponges under the legs of a heavy table supporting the apparatus. It is preferable to screw the supporting bracket on a wall. I have, indeed, been able to secure a magnification of ten million times with my Magnetic Crescograph in public demonstrations in busy London,

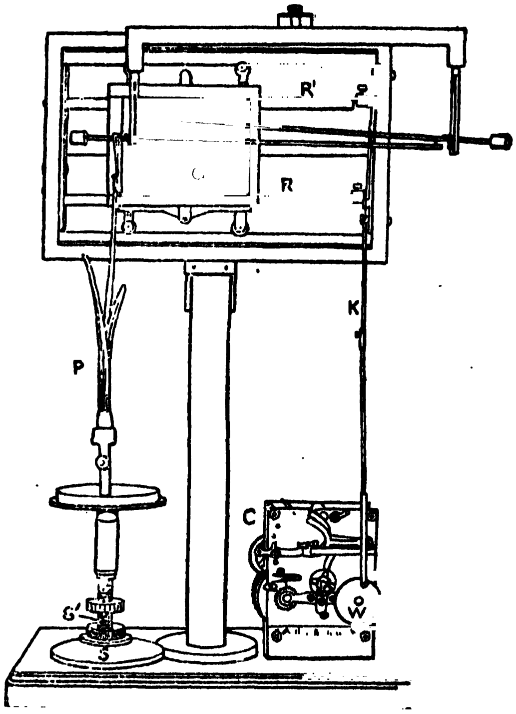

FIG. 1.—The High Magnification Crescograph. P, plant; S, S', micrometer screw for raising or lowering the plant; C, clockwork for periodic oscillation of plate; K, crank; W, rotating wheel.

the indication of the instrument being quite unaffected by the street traffic. In Fig. 2*c* is given the record on a moving plate taken with the High Magnification Crescograph. A dead twig had been substituted for the growing plant, and a perfectly horizontal record demonstrated the absence not only of growth, but also of all disturbance. There is an element of physical change in experiments on variation of the rate of growth under artificially raised temperature. In order to determine its character and extent, a record was taken with the dead twig of the effect of raising the temperature of the plant-chamber through 10° C. The record shows that there was an expansion during rise of temperature, which, however,

[1] For a fuller account see the author's "Researches on Growth and Movement in Plants by means of the High Magnification Crescograph," Proc. Roy. Soc., B, vol. cx., 1919. (The diagrams are reproduced with the kind permission of the Royal Society.) Also the following works published by Messrs. Longmans, Green, and Co.:—"Response in the Living and Non-living" (1902); "Plant Response" (1906); "Comparative Electro-physiology" (1907); "Irritability of Plants" (1913); "Life-movements in Plants," vols. i. and ii. (1918–19).

reached a limit, the record becoming once more horizontal. The obvious precaution to be taken in the study of variation of growth under change of temperature is to wait for several minutes for the attainment of steady temperature. The elongation caused by physical change abates in a short time, whereas the physiological variation in the rate of growth is persistent.

In Fig. 2*a* is given a record of growth of *Scirpus kysoor*; the growth per second magnified ten thousand times is 9·5 mm. The absolute rate of growth per second is therefore 0·00095 mm., or 0·95μ, where μ or micron is 0·001 mm.

Effect of Stimulus on Growth.—A generalisation was obtained that *all forms of stimuli, mechanical, electrical, or radiational, induce a retardation of the rate of growth;* under increasing intensity or duration of stimulus this retardation may culminate in an arrest of growth or even in actual contraction of the organ. As regards radiation, all rays of the vast æthereal spectrum (with the exception of red and yellow rays which cause photo-synthesis) are found to cause response by modifying the rate of growth of the plant. I have thus been able to obtain records of response of plants to long æther waves employed in signalling through space. (NATURE, October 30, 1919.)

Effect of Sub-minimal Stimulus.—A very unexpected result was obtained under the action of sub-minimal stimulus, which induced an *acceleration* of growth instead of *retardation* under moderate intensity. This I find to be true of stimulation as diverse as that caused by electric shock, by light, and by chemical agents. A strikingly practical result was obtained with certain poisons which in normal doses killed the plant, but which in quantities sufficiently minute acted as an extraordinarily efficient agent for stimulating growth, the treated plants growing far more vigorously and flowering much earlier. It is only by the discovery of laws of growth that any marked advance in scientific agriculture will be rendered possible. We have been using a few stimulating agents, whereas there are thousands of the action of which we have no conception. The rule-of-thumb methods often employed in the application of a few chemical agents and of electricity have not been uniformly successful. The cause of the anomaly is found in the discovery of an important factor—namely, the dose of application—which had not hitherto been taken sufficiently into account.

The Balanced Crescograph.—The high sensitiveness already secured has been very greatly enhanced by the employment of the Null Method or the Method of Balance, where the rate of up-movement of growing tip is exactly compensated by the down-movement of the plant. A train of revolving clock-wheels, actuated by the fall of a weight, lowers the plant at the required rate. The exact adjustment is obtained by the right- or left-handed turning of a screw which regulates the governor. In this way the rate of growth becomes exactly compensated, and the recorder now dots a horizontal line instead of the former curve of ascent. The turning of the adjusting screw also moves an index against a circular scale so graduated that its reading at once gives the rate at which the plant is growing at the moment. When balanced, the recording apparatus is extremely sensitive, the effect of any change in the environment, however slight, being at once indicated by the upset of balance with the up or down movement of the indicator. I have in this way been able to detect induced variation in the rate of growth so exceedingly minute as $\frac{1}{2000000000}$ in. per second. An illustration of the delicacy of the method will be found in the record given in Fig. 3, on the effect of carbonic acid gas on growth; there is an immediate acceleration of growth (up-record), which continues for two and a half minutes; this is followed by retardation, as shown by the down curve. With diluted carbonic acid the acceleration may persist for a considerable time. As another instance of the delicacy of the method of balance, I obtained a decided response of the plant to the light so fleeting as that of a single electric spark the duration of which is of the order of $\frac{1}{100000}$ second.

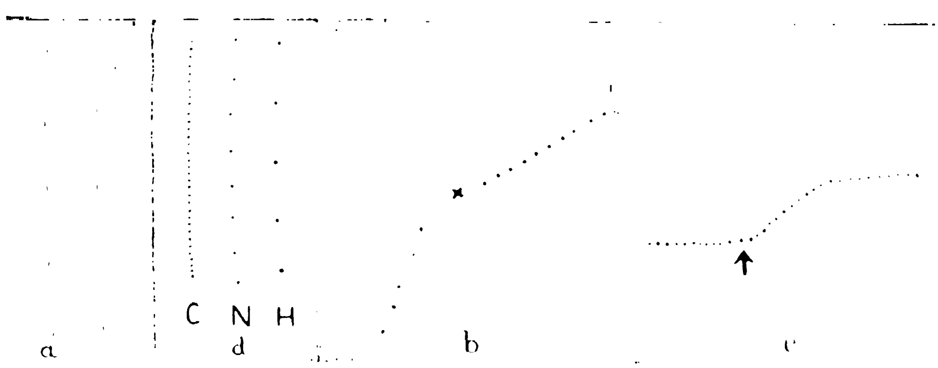

FIG. 2.—Crescographic records. *a*, Successive records of growth at intervals of 1 second; ×10,000, with a stationary plate. Effect of temperature: *d*, N, normal rate of growth; C, retarded rate under cold; H, enhanced rate under warmth; *b*, record on moving plate where diminished slope of curve denotes retarded rate under cold; *c*, horizontal record showing absence of growth in dead branch; physical expansion on application of warmth at arrow followed by horizontal record on attainment of steady temperature.

The Magnetic Crescograph.—There is a limit to the magnification obtained by a compound

system of levers; an additional lever increases the weight and friction. For special research and for public demonstration a still higher magnification is necessary, and this I secured by the invention of the Magnetic Crescograph, where a fine magnetised lever causes by its movement a rotation of a suspended system of astatic needle with its attached mirror. By graduated approach of the suspended needle to the lever the magnification may be continuously increased from a million to ten million times. A concrete idea of the stupendous magnification will be obtained if we imagine the slow pace of the proverbial snail magnified ten million times. The 15-in. gun of the *Queen Elizabeth* throws out a shell with a muzzle-velocity of 2360 ft. per sec., but the crescographic snail would move twenty-four times faster than the cannon shot. The magnification of ten million times was obtained with a single lever, but a double lever will enlarge it a hundredfold—that is to say, it will give a total magnification of a thousand million times. The importance of this device for research in other branches of science is sufficiently obvious. For general purposes a magnification of a million times is sufficient; with ordinary precaution the apparatus may be rendered free from mechanical disturbance, and the zero-keeping quality of the indicating spot of light is quite perfect.

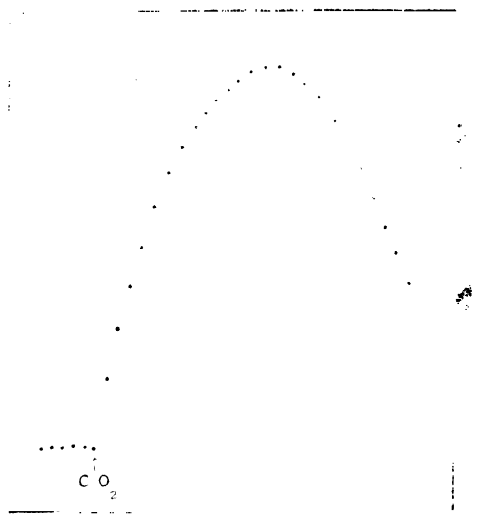

FIG. 3.—Record showing the effect of carbonic acid gas. Horizontal line at the beginning indicates balanced growth. Application of carbonic acid gas induces enhancement of growth, shown by up-curve, followed by depression, exhibited by down-curve. Successive dots at intervals of ten seconds.

The following account of an experiment in demonstration of physiological response in a growing plant will be found interesting. The normal growth of the plant was indicated by the excursion of the spot of light through 6 metres in 10 secs. On introduction of chloroform vapour to the plant-chamber there was an immediate enhancement of the rate of growth, the spot of light moving three times faster. Continued action of the vapour of chloroform caused, however, a depression and arrest of growth; finally, there was a sudden contraction, which proved to be the spasm of death. Similar effects were produced by various poisons like the solution of potassium cyanide.

After this brief account of the very sensitive methods for the detection and record of the effect of stimulus on growth, I propose in another article to describe results which will offer an explanation of the tropic movements in plants induced by various stimuli of the environment.

Isotopes and Atomic Weights.

By DR. F. W. ASTON.

IN the atomic theory put forward by John Dalton in 1801 the second postulate was: "Atoms of the same element are similar to one another and equal in weight." For more than a century this was regarded by chemists and physicists alike as an article of scientific faith. The only item among the immense quantities of knowledge acquired during that productive period which offered the faintest suggestion against its validity was the inexplicable mixture of order and disorder among the elementary atomic weights. The general state of opinion at the end of last century may be gathered from the two following quotations from Sir William Ramsay's address to the British Association at Toronto in 1897:—

There have been almost innumerable attempts to reduce the differences between atomic weights to regularity by contriving some formula which will express the numbers which represent the atomic weights with all their irregularities. Needless to say, such attempts have in no case been successful. Apparent success is always attained at the expense of accuracy, and the numbers reproduced are not those accepted as the true atomic weights. Such attempts, in my opinion, are futile. Still, the human mind does not rest contented in merely chronicling such an irregularity; it strives to understand why such an irregularity should exist. . . . The idea . . . has been advanced by Prof. Schutzenburger, and later by Mr. Crookes, that what we term the atomic weight of an element is a mean; that when we say the atomic weight of oxygen is 16, we merely state that the average atomic weight is 16; and it is not inconceivable that a certain number of molecules have a weight somewhat higher than 32, while a certain number have a lower weight.

This idea was placed on an altogether different footing some ten years later by the work of Sir Ernest Rutherford and his colleagues on radioactive transformations. The results of these led inevitably to the conclusion that there must exist elements which have chemical properties identical for all practical purposes, but the atoms of

which have different weights. This conclusion has been recently confirmed in a most convincing manner by the production in quantity of specimens of lead from radio-active and other sources, which, though perfectly pure and chemically indistinguishable, give atomic weights differing by amounts quite outside the possible experimental error. Elements differing in mass but chemically identical and therefore occupying the same position in the periodic table have been called "isotopes" by Prof. Soddy.

At about the same period as the theory of isotopes was being developed by the radio chemists at the heavy end of the periodic table an extremely interesting discovery was made by Sir J. J. Thomson, which carried the attack into the region of the lighter and non-radio-active elements. This was that, when positive rays from gases containing the element neon were analysed by electric and magnetic fields, results were obtained which indicated atomic weights roughly 20

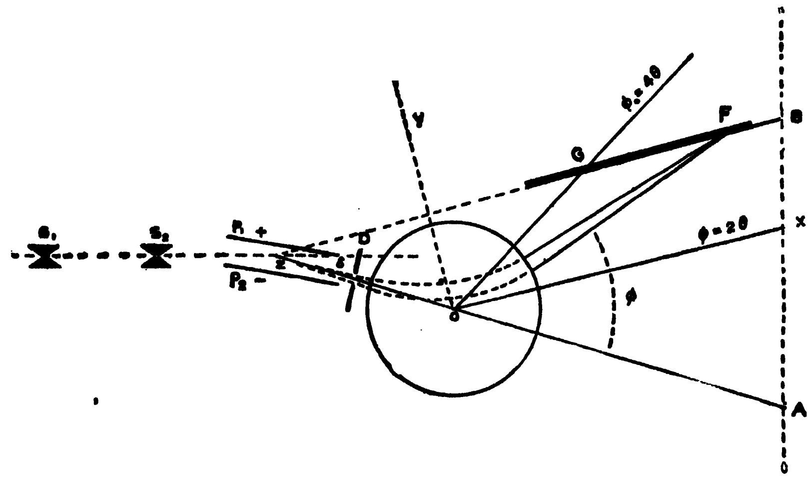

FIG. 1.—Diagram of positive-ray spectrograph.

and 22 respectively, the accepted atomic weight being 20·2. This naturally led to the expectation that neon might be a mixture of isotopes, but the weight 22 might possibly be due to other causes, and the method of analysis did not give sufficient accuracy to distinguish between 20·0 and 20·2 with certainty. Attempts were made to effect partial separation first by fractionation over charcoal cooled in liquid air, the results of which were absolutely negative, and then by diffusion, which in 1913 gave positive results, an apparent change in density of 0·7 per cent. between the lightest and heaviest fractions being attained after many thousands of operations. When the war interrupted the research, it might be said that several independent lines of reasoning pointed to the idea that neon was a mixture of isotopes, but that none of them could be said to carry the conviction necessary in such an important development.

By the time work was started again the isotope theory had been generally accepted so far as the radio-active elements were concerned, and a good deal of theoretical speculation had been made as to its applicability to the elements generally. As separation by diffusion is at the best extremely slow and laborious, attention was again turned to positive rays in the hope of increasing the accuracy of measurements to the required degree. This was done by means of the arrangement illustrated in Fig. 1. Positive rays are sorted into an extremely thin ribbon by means of parallel slits S_1 S_2, and are then spread into an electric spectrum by means of the charged plates P_1 P_2. A portion of this spectrum deflected through an angle θ is selected by the diaphragm D and passed between the circular poles of a powerful electromagnet O the field of which is such as to bend the rays back again through an angle ϕ more than twice as great as θ. The result of this is that rays having a constant mass (or more correctly constant m/e) will converge to a focus F, and that if a photographic plate is placed at GF as indicated, a *spectrum dependent on mass alone* will be obtained. On account of its analogy to optical apparatus, the instrument has been called a positive-ray spectrograph and the spectrum produced a mass-spectrum.

Fig. 2 shows a number of typical mass-spectra obtained by this means. The number above the lines indicates the masses they correspond to on the scale O=16. It will be noticed that the displacement to the right with increasing mass is roughly linear. The measurements of mass made are not absolute, but relative to lines the mass of which is known. Such lines, due to hydrogen, carbon, oxygen, and their compounds, are generally present as impurities or purposely added, for pure gases are not suitable for the smooth working of the discharge tube. The two principal groups of these reference lines are the C_1 group due to C (12), CH (13), CH_2 (14), CH_3 (15), CH_4 or O (16), and the C_2 group 24–30 containing the very strong line 28 C_2H_4 or CO. In spectrum i. the presence of neon is indicated by the lines 20 and 22 situated between these groups. Comparative measurements show that these lines are 20·00, 22·00, with an accuracy of one-tenth per cent., which removes the last doubt as to the isotopic nature of neon.

The next element investigated was chlorine; this is characterised by four strong lines 35, 36, 37, 38, and fainter ones at 39, 40; there is no trace of a line at 35·46, the accepted atomic weight. From reasoning which cannot be given here in detail it seems certain that chlorine is a complex element, and consists of isotopes of atomic weights 35 and

37, with possibly another at 39. The lines at 36, 38 are due to the corresponding HCl's.

Particles with two, three, or more electronic charges will appear as though having half, a third, etc., their real mass. The corresponding lines are called lines of the second, third, or higher order. In spectrum ii. the lines of doubly charged chlorine atoms appear at 17·5 and 18·5. Analyses of argon indicate that this element consists almost entirely of atoms of weight 40, but a faint component 36 is also visible. Spectra v. and vi. are taken with this gas present; the former shows the interesting third order line at 13⅓. Krypton and xenon give surprisingly complex method (see *Phil. Mag.*, May, 1920, p. 621), some results of which are given in spectrum vii., hydrogen is found to be 1·008, which agrees with the value accepted by chemists. This exception from the whole number rule is not unexpected, as on the Rutherford "nucleus" theory the hydrogen atom is the only one not containing any negative electricity in its nucleus.

The results which have so far been obtained with eighteen elements make it highly probable that the higher the atomic weight of an element, the more complex it is likely to be, and that there are more complex elements than simple. It must be noticed that, though the whole number rule

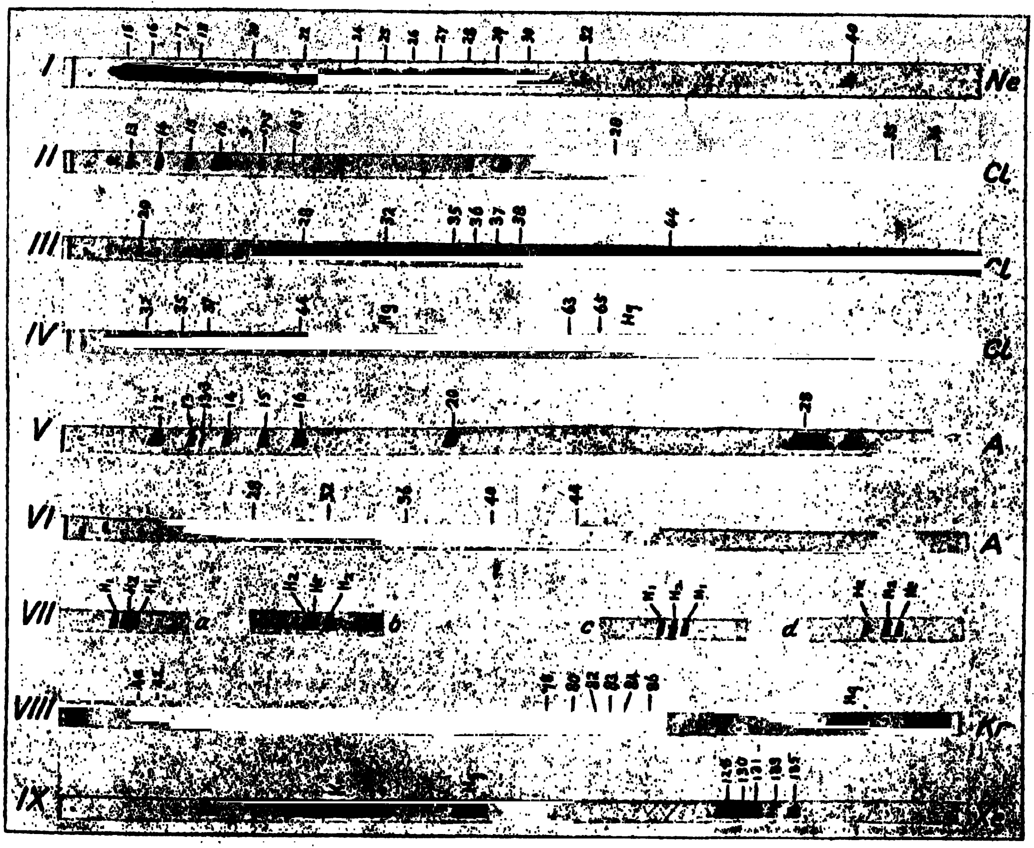

FIG. 2.—Typical mass-spectra.

results; the former is found to consist of no fewer than six isotopes, the latter of five (spectra viii. and ix.). Mercury is certainly a complex element probably composed of five or six isotopes, two of which have weights 202 and 204; its multiply charged atoms give the imperfectly resolved groups, which are indicated in several of the spectra reproduced in Fig. 2.

By far the most important result obtained from this work is the generalisation that, with the exception of hydrogen, all the atomic weights of all elements so far measured are exactly whole numbers on the scale O=16 to the accuracy of experiment (1 in 1000). By means of a special asserts that a pure element must have a whole number atomic weight, there is no reason to suppose that all elements having atomic weights closely approximating to integers are therefore pure.

The very large number of different molecules possible when mixed elements unite to form compounds would appear to make their theoretical chemistry almost hopelessly complicated, but if, as seems likely, the separation of isotopes on any reasonable scale is to all intents impossible, their practical chemistry will not be affected, while the whole number rule introduces a very desirable simplification into the theoretical aspects of mass.

Obituary.

MAJOR-GEN. WILLIAM CRAWFORD GORGAS, K.C.M.G.

IN St. Paul's Cathedral on July 9 a very remarkable tribute was paid to one who may fittingly be termed a Napoleon of Hygiene. On that day a military funeral was accorded to the remains of Major-Gen. William Crawford Gorgas, Surgeon-General of the United States Army and president of the American Medical Association. The impressive service was attended by a large concourse, including the Director-General of the Army Medical Department, who represented the King, the Director-General of the Medical Department of the Navy, the Presidents of the Royal Colleges of Physicians and Surgeons, the Presidents of the Royal Society of Medicine and the Royal Society of Tropical Medicine and Hygiene, and representatives of other learned societies and scientific institutions. Had the late Gen. Gorgas been a British subject such a tribute to his life and work would have been sufficiently noteworthy, but that a citizen and soldier of the United States should be honoured by these funeral rites is a unique testimony, not only to the man who fought and conquered yellow fever, but also to preventive medicine generally.

It is right that it should be so, and to no one could such an honour be more fittingly paid than to the man who devoted himself heart and soul to making the tropics healthy and habitable and, above all others, translated the pioneer scientific work of Laveran, Manson, Ross, Grassi, Finlay, and others into action.

Gorgas's life, one of ceaseless activity in the cause of science and humanity, began on October 3, 1854, when he was born at Mobile, Alabama, and terminated in the Queen Alexandra Military Hospital, London, on July 3. Death overtook him on his way to a new field of work, for he was taken seriously ill in England when *en route* to the West Coast of Africa with the view of studying the yellow fever problem there, a problem by no means solved and differing in some respects from that which presented itself in the New World.

Gorgas was a son of the South, his father being Gen. Josiah Gorgas, of the Confederate States Army, and his mother a member of a Southern family. He received his medical training at the Southern University, Tennessee, where he graduated A.B., and in 1879 he qualified M.D. at the Bellevue Hospital Medical College of New York University, thereafter holding a house appointment in the hospital.

In 1880 Gorgas joined the United States Army as a surgeon and served in various parts of the country, first coming into contact with yellow fever in Western Texas and himself suffering from an attack of the disease. His promotion in the service was rapid, and, his bent being towards the preventive side of medicine, the year 1898 saw him appointed Chief Sanitary Officer of Havana. At that time Havana was a hot-bed of yellow fever, and Surgeon-Major Gorgas found plenty of scope for his energies. While his colleagues Reed, Carroll, Agramonte, and Lazear established the *rôle* of *Stegomyia fasciata* as the vector of the then unknown parasite of yellow fever, Gorgas, as soon as he was certain of the facts, embarked wholeheartedly on an anti-mosquito campaign which in a remarkably short space of time freed Havana from the scourge of "Yellow Jack." It was then that he first displayed to the full those qualities of drive, tact, tenacity, firmness, and resolution which eventually gained for him the proud titles of "a Master-Administrator of tropical hygiene" and of "a Hercules of modern hygiene."

Gorgas had a wonderful way of getting at the heart of things. He was essentially practical, and this practicality, combined with enthusiasm and a devotion almost religious in character, found a still greater field in Panama. He was rewarded for his labours at Havana by being promoted Colonel and Assistant Surgeon-General in the United States Army, and it was in 1904 that he was sent to the famous isthmus to report upon the sanitary condition of the Canal Zone and to become ere long Chief Health Officer of an area which for centuries had been notorious for its unhealthiness, a region devastated by malaria and yellow fever and a veritable forcing-house for tropical pathology.

At first Gorgas had many difficulties. He was up against the Canal Commissioners; he was at loggerheads with the engineers; he found himself hampered by red-tape and restrictions of all kinds. Fortunately, the reins of power were at that time held in the United States by a man of very similar calibre to himself, and Theodore Roosevelt, realising all that depended on Gorgas's work, and having every sympathy with him and none for hide-bound traditions, swept away the obstacles from his path, and gave him a free hand and full responsibility. This was all Gorgas wanted. He knew, thanks to the work of Manson, Ross, and Finlay in the first place, and to the labours and sacrifices of his colleagues at Havana in the second, that he was on sure ground, and, backed loyally by the governor of the Canal Zone, Judge Magoon, he embarked with a worthy band of helpers and abundant sinews of war upon a campaign which speedily routed the forces of disease and death, rendered the Canal Zone not only habitable, but also healthy, and which will stand for all time as a monument to what can be done when science and administrative hygiene are given ample powers.

The results achieved induced Gorgas to put forward the theory, advanced also by Sambon and others, that if insanitary conditions are removed the white man can not only live and labour in the tropics, but also propagate his race there, and that his descendants will be healthy and virile. It is too early yet to say that this is wholly the case, but it is interesting to note what Gorgas said about this important question. Speaking of his work, he wrote:—

The real scope of tropical sanitation, which has been almost entirely developed within the last fifteen or twenty years, I believe, will extend far beyond our work at Panama. Everywhere in the tropics to which the United States has gone in the past fifteen years it has been shown that the white man can live and exist in good health. This has occurred in the Philippines, in Cuba, and in Panama, but the demonstration has been most prominent and spectacular at Panama, and therefore has attracted there the greatest world-wide attention. Here among our large force of labourers we had for ten years some ten thousand Americans—men, women, and children. Most of these American men did hard manual labour, exposed to the sun, rain, and weather conditions day in and day out, yet during that time their health remained perfectly good, just as good as if they were working at home. The same remark as to health would apply to the four thousand women and children who lived at Panama with their husbands and fathers. Both the women and children remained in as good condition as they would have been had they lived in the United States. This condition at Panama, I think, will be generally received as a demonstration that the white man can live and thrive in the tropics. The amount of wealth which can be produced in the tropics for a given amount of labour is so much larger than that which can be produced in the temperate zone by the same amount of labour that the attraction for the white man to emigrate to the tropics will be very great when it is appreciated that he can be made safe as to his health conditions at a small expense. When the great valleys of the Amazon and of the Congo are occupied by a white population more food will be produced in these regions than is now produced in all the rest of the inhabited world.

Panama made Gorgas famous; the Royal Society awarded him its Buchanan medal; the University of Oxford made him an honorary D.Sc.; the Liverpool School of Tropical Medicine presented him with its Mary Kingsley medal; and he was not forgotten in America. He did not, however, rest upon his oars. In 1913 the Chamber of Mines at Johannesburg sought his advice as regards the prevention of pneumonia among native miners on the Rand, and he proceeded to South Africa and carried out an investigation which led to useful results. He then turned his attention to South America, for the dream of his life—and no vain dream—was to stamp yellow fever out of the world. He made a survey of the endemic foci in South America, and then started to obliterate the worst of them at Guayaquil, in Ecuador. Here, again, his efforts and those of his assistants were crowned with success, and it is a tribute to his tact and discretion that so much could be accomplished in one of the lands of *mañana*, as some of the Spanish South American republics may be not inaptly called.

As director of the International Health Board of the Rockefeller Institute, a post to which he was appointed on the completion of the Panama Canal, Gorgas had excellent facilities for travel and investigation, and he became an apostle, as well as a priest, of the goddess Hygeia. As Surgeon-General of the United States Army, he had to organise the medical service for the Great War, and during the war he visited both France and Serbia, retiring, however, from the United States Army in 1918 under the age-rule.

Scarcely had hostilities ceased when his attention turned again to yellow fever, and along with Surgeon-Gen. Noble and Dr. Guiteras, of Havana, he was, as stated, on his way to the African West Coast, when he was stricken down by what proved to be a fatal illness. On his sick bed he was visited by the King, who conferred a K.C.M.G. upon him, and just before he took ill, when he was in Brussels at the Congress of the Royal Institute of Public Health, he was presented with the Harben gold medal, while at the recent annual meeting of the British Medical Association the University of Cambridge conferred upon him its honorary LL.D.

Gorgas died full of honours, if not of years. His work received its rightful recognition, and if he died comparatively early it must be remembered that his life was a very strenuous one, spent to a large extent in hot climates, and that he came very near to realising his lifelong ambition.

He was a man of resource and courage, but he was also a man with a kindly heart and a gratifying sense of humour. He knew how to handle those serving under him, and how to get the best out of them, while he gave credit where credit was due.

It has been said of him, sometimes bluntly, sometimes even rudely, that, in the strict sense of the term, he was not a scientific worker, but the fact remains that Gorgas worked ever on strictly scientific lines, and that the moment a scientific truth had been enunciated he was up and doing in order to apply it for the welfare of mankind. Without men of his stamp the labour of the microscopists would to a large extent be futile. His art was the natural corollary of the laboratory, and no more efficient exponent of it can be imagined.

As his coffin, shrouded by "Old Glory," borne by stalwart British Guardsmen, flanked by British medical officers of high rank, and followed by his widow and a distinguished company, passed up the aisle of St. Paul's, it was in keeping with his life's work that, amongst the wreaths waiting to be placed upon it, was one sent as a token of remembrance and esteem by his friend Sir Patrick Manson.

Notes.

THE exhibits of the Research Department, Woolwich, at the Imperial War Museum, Crystal Palace, illustrate some of the work vital to the war which was done there, and incidentally our unpreparedness, as much of it might have been done before. Amongst the specimens shown are the six isomers of T.N.T., isolated whilst devising new processes for the manufacture of the symmetrical variety, and for cheaply eliminating the undesirable isomers—a problem not yet fully solved. There are also specimens of amatol, which has largely replaced T.N.T. as a shell-filling; tetranitromethyl aniline, which is of increasing use as an initiator of detonation in others; trinitrobenzene, which should have a future, and many others. The exhibits of fragments of shells detonated by picric acid, T.N.T., and amatol respectively show by the relative numbers of the fragments that picric acid still remains our most shattering shell explosive, and, by the minuteness of most, how limited the killing range of such shells really is. The specimen of R.D.B. cordite illustrates how, when through lack of foresight our supply of acetone failed, our chemists and distilleries saved the situation by providing soluble nitrocellulose and alcohol-ether to gelatinise it. The sections of gaines show how the problem of detonating insensitive shell-fillings was solved during the war by employing a series of explosives in the detonator, and accomplishing in several steps what could not be done with certainty in one. The specimens which display the eroding effect of hot gases on gun-tubes present a problem to chemists which will probably be solved by the invention of a new alloy. An excellent series of X-ray photographs shows that great progress has been made in the penetration of metals. Internal flaws in parts are revealed, and also the internal structure of ammunition—an important matter when captured ammunition has to be examined and dissected. There are many other exhibits of interest.

THE appeal which the chairman of the Brent Valley Bird Sanctuary makes in our correspondence columns for funds with which to buy and endow the reserve which the Selborne Society has maintained for eighteen years will commend itself to most naturalists. It is as important to rear two useful birds as it is to make two ears of corn grow where there was but one before, and the sanctuary has done more than this. Not only has it enabled birds to build undisturbed near London, but its example has been followed elsewhere, and in thousands of gardens have birds been brought up where there were no fledglings previously. This is through the nesting-boxes which the committee has sent out. Such work should go on. A permanent sanctuary within the London area would be an excellent memorial to Gilbert White and crown the efforts of the Selborne Society. Although the gift of the purchase money or some substantial contributions would bring the endeavour to an earlier completion, we imagine that the more subscribers there are the better pleased would the committee be, and small amounts would therefore be welcomed.

THE fifty-seventh annual general meeting of the British Pharmaceutical Conference will be held at Liverpool on July 19–23 under the presidency of Mr. C. A. Hill, managing director of The British Drug Houses, Ltd., who will deliver his presidential address at the Royal Institution, Liverpool, on Tuesday, July 20. The British Pharmaceutical Conference is an organisation established in 1863, and during the fifty-six years of its existence it has made at its annual meetings a total addition of more than a thousand original researches to the common stock of chemical and pharmaceutical knowledge. Among the subjects of the scientific papers to be read at the forthcoming meeting are: A New Method for the Estimation of Cineole in Eucalyptus Oils; The Determination of Hydrocyanic Acid, of Nitrate in Bismuth Carbonate, and of Free Acetic Acid in Acetylsalicylic Acid; Aconite Alkaloids: An Improved Method for their Estimation; and The Detection of Inorganic Phosphate in Glycerophosphates.

WITH the view of obtaining further evidence as to the relationship of the Early Mousterian palæolithic flint implements to the Glacial Chalky Boulder Clay, excavations will be carried out shortly at High Lodge, Mildenhall, Suffolk, by Prof. J. E. Marr, Mr. J. Reid Moir, Mr. Reginald Smith, Mr. Henry Bury, and Mr. M. C. Burkitt. The owner of the High Lodge property, Sir Henry Bunbury, Bart., having given permission for the diggings to be conducted, it is hoped that it may be possible to ascertain with certainty whether the well-known brick-earth of Mousterian age occurring at this spot is younger or older than the Boulder Clay with which it is intimately associated. A full account of the excavations and the conclusions arising therefrom will be published in due course.

THE following elections in connection with the Royal College of Surgeons of England are announced:—*President:* Sir Anthony A. Bowlby. *Hunterian Professors:* Mr. C. W. G. Bryan, Mr. A. G. T. Fisher, Mr. W. S. Handley, Mr. W. G. Howarth, Prof. A. Keith, and Mr. H. Platt. *Arris and Gale Lecturers:* Mr. J. F. Dobson, Dr. F. W. Edridge-Green, and Mr. J. H. Evans. *Erasmus Wilson Lecturer:* Prof. S. G. Shattock. *Arnott Demonstrator:* Prof. A. Keith. *Pathological Curator:* Prof. S. G. Shattock. *Physiological Curator:* Mr. R. H. Burne. *Honorary Curator of the Odontological Collection:* Sir Frank Colyer. Sir D'Arcy Power is to deliver the next Thomas Vicary lecture.

THE VERY REV. DR. W. R. INGE, Dean of St. Paul's, is president for the new session of the Aristotelian Society which will open in November next.

THE Sir Alfred Jones Laboratories of the Liverpool School of Tropical Medicine will be officially opened by Lord Leverhulme on Saturday, July 24, at 2.30. The presentation of Mary Kingsley memorial medals will also be made.

SIR ROBERT JONES has been awarded the Cameron prize of the University of Edinburgh in recognition of his work in orthopædics. Earlier recipients of the prize, which is of the value of about 150*l.*, were Pasteur, Lord Lister, and Sir Lauder Brunton.

DR. SEYMOUR HADWEN has resigned his position as Chief Pathologist in charge of the Biological Laboratory, Health of Animals Branch, Canadian Department of Agriculture, Ottawa, Canada, and become Chief Pathologist in the Reindeer Investigations of the Bureau of Biological Survey, U.S. Department of Agriculture.

WE are informed by the Department of Scientific and Industrial Research that the Research Association for the cutlery industry has been approved by the Department as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The secretary of the Committee engaged in the establishment of this association is Mr. W. H. Bolton, P.O. Box 49, Sheffield.

THE Royal Statistical Society has opened a register of the names of persons eligible for statistical posts. It has from time to time been asked to recommend qualified statisticians, and has taken this means of bringing those who have appointments to offer into touch with suitable applicants. A list of names and qualifications is now available, and the secretary (9 Adelphi Terrace, W.C.2) will be glad to furnish information accordingly.

WE learn from *Science* that Prof. L. H. Bailey is reorganising the American Pomological Society, of which he is president, and establishing junior branches in a number of agricultural colleges in the United States and Canada. It is proposed under the new scheme that the society shall give consideration to such national affairs as touch the growing of fruits, *e.g.* legislation, quarantine, export, transportation, and standardising methods.

CAPT. W. J. RUTHERFORD has reprinted from "The History of the Berwickshire Naturalists' Club" (vol. xxiv.) a paper on "A Border Myth: The Standing Stones at Duddo." The local folklore accounts for their origin by supposing that the stones are the petrified bodies of a gang of field-workers who profaned the Sabbath by going into a field singing and thinning a crop of turnips, while the leader was thrown on his back and lies prostrate to this day. Capt. Rutherford compares the legend with that attached to the "Maidens" or "Merry Maidens" and the "Hurlers" in Cornwall. The story is not uncommon, and it would not be difficult to quote other parallels.

THE report of the Felsted School Scientific Society for 1918 and 1919 is welcome evidence of the place given to scientific pursuits in an up-to-date school. The natural history notes, which predominate, reach a high standard and contain many interesting observations on the local appearance and movements of migratory birds, while the photographs which have been selected for reproduction say much for the skill and patience of the young naturalists. The report shows how greatly the progress of a school society depends upon the guidance of an enthusiastic master. It is gratifying to see from the balance-sheet that the governors, by a generous contribution to the funds of the society, give evidence of their belief in the value of Nature-study, and their faith is well founded, for the recording of detailed observations, whether of rainfall or temperature or migration, is a sowing of the seeds of the scientific habit and the love of truth.

UNDER the title "The Birds of Eastern Canada," the Canadian Department of Mines has issued a memoir—No. 3 of its Biological Series—by P. A. Tavener. This has been written "to awaken and, where it already exists, to stimulate an interest, both æsthetic and practical, in the study of Canadian birds and to suggest the sentimental, scientific, and economic value of that study; to assist in the identification of native species; and to furnish the economist with a ready means of determining bird friend from bird foe . . .; to present in a readily accessible form reliable data upon which measures of protective legislation may be based; to point out some of the pitfalls that have caught the inexperienced in the past; and to suggest methods for their future avoidance." To accomplish these desirable ends, the memoir treats of all the species with which the ordinary observer is likely to meet "between the Atlantic coast and the Prairies north of the International Boundary." It is prefaced by some general remarks on classification, geographical distribution, migration, and protection, and by an illustrated key to the characters of the groups to which the various species belong. The main portion of the work deals with 766 selected birds, and shortly describes their plumage, haunts, nesting, economic status, and distribution in Eastern Canada: many of them are depicted in the series of coloured plates which forms the concluding portion of this useful memoir.

IN the interests of commerce itself it is becoming increasingly plain that where the exploitation of wild animals is concerned men of science, and not the captains of industry, must determine the levy which any given species can stand without endangering its safety. The urgent need for the speedy recognition of this fact is very emphatically shown in a series of able essays published in the form of a bulletin by the Scripps Institution for Biological Research of the University of California (No. 9). Where all are of such surpassing excellence it is difficult to select any one of these essays for special mention. But since a choice must be made, it shall fall upon that of Dr. Evermann, who surveys the present position of the Northern fur-seal. He throws a lurid light on the attitude of the non-scientific legislator. Even Departments of State, he shows, for the sake of present revenue, will adopt covertly hostile methods to suppress the findings of scientific men appointed for the express purpose of investigating the conditions of the sealing industry, if such findings seem to threaten the earnings of that industry. The fact that, unless wise methods of conservation are adopted, the industry will presently extinguish itself seems entirely to be lost sight of in the desire to secure immediate revenue. "Take the cash in hand and waive the rest" seems to be the motto pursued. Those interested in the salmon fisheries contend that the seals eat vast quantities of these fish, and are therefore injurious to the fishing interests. Yet no attempt has so far been made to discover what fish really constitutes

the staple diet of the fur-seal. This aspect of the problem adds to its complexity, since it affects conflicting interests. At the same time it emphasises the need for immediate action, not for academic discussion.

THE many friends of the veteran geologist, Mr. Henry Keeping, who was born near Milton, on the Hampshire coast, in 1827, will welcome his simple and unaffected "Reminiscences," published as a pamphlet by F. W. Talbot, Sussex Street, Cambridge (price 1s. 6d. post free). A characteristic portrait appears on the cover. Anecdotes of Sedgwick and of the early days of collecting in Devonshire and the Isle of Wight form pleasant reading. The story of the plump farmer in the Fenland who checked a disaster by sitting in the gap of a broken dyke is told with humorous appreciation.

PROF. PIERRE TERMIER, in a paper on "Les Océans à travers les âges" (*Revue Scientifique*, May 8, 1920), emphasises the differences in structure of the Atlantic and Pacific Oceans, and regards the deep-water ring around the central area of the latter as a persistent feature of the crust, liable to disturbances, but not to elevation as dry land. The Indian Ocean, on the other hand, is post-Jurassic and the Atlantic is post-Miocene. The narrowing of the continents southwards is not a primary feature of a tetrahedral earth, but results from the widening of these comparatively modern areas of subsidence as they approach the south.

THE *Geographical Review* (New York) for March, 1920, contains two articles of especial interest to British readers. The first is by Lieut. Leo Walmsley on "The Recent Trans-African Flight," with several photographic illustrations. The writer's wide knowledge of Eastern Africa and his success as a scientific observer even when fighting from his aeroplane fully justify his remark that "Africa, as seen from the air, is one of the most wonderful of all countries. . . . A civilised country seen from the air is simply a gigantic mosaic . . . the airscape of Central Africa is as untamed and irregular as that of the moon." The second article is by Mr. C. R. Dryer on "Mackinder's 'World Island' and its American 'Satellite.'" The author cleverly shows, on Mollweide's projection, the American continents as a "world ring" round about the "world island," and pictures the people of that world ring, which has no barbarous heartland, as ready to come to the aid of the coastal races that stand for civilisation in the world island.

STONYHURST College Observatory has recently issued the results of meteorological and magnetical observations for 1919 with a report and notes by the director, the Rev. A. L. Cortie, S.J. The results with the report occupy 55 pages, and details of the observations are given with great precision for the several months and for the year. The observatory has long since been associated with the Meteorological Office, and the Monthly Weather Report publishes many of the results. The monthly mean temperature is obtained in two ways, from the mean of the highest and lowest daily readings and from the mean of the readings at 9 a.m. and 9 p.m., both means being corrected by Glaisher's tables. The thermometers are mounted 7 ft. above the ground in a Stevenson screen; why in this case should not the height above ground be 4 ft., the normal height for uniformity? Taken as a whole, 1919 was drier and colder than the normal, and every individual month was cold with the exception of May and December. Bright sunshine for the year was 25 hours less than the normal. Rainfall was nearly 6 in. deficient, although the rainy days were only two fewer than usual. October was relatively the driest month, rainfall being only about 50 per cent. of the average. Magnetic observations and disturbances are popularly explained, and afford considerable information for obtaining uniformity of results. Sun-spot activity, which had steadily declined since August, 1917, and throughout 1918, revived in 1919. The seismograph, which for a time had been thrown out of action, is said to be now working satisfactorily.

MR. J. I. GRAHAM, research chemist at the Bentley Collieries, Doncaster, has devised a very convenient and portable apparatus for the estimation of small quantities of carbon monoxide in the air of mines. It consists of a vessel containing a known volume of the sample, which can be introduced by running water out of the vessel. By operating a three-way tap and blowing water into the vessel the sample may be passed into iodine pentoxide contained in a U-tube heated to 90°–150° C. In examining air in the mine the temperature is maintained by hot oil contained in a thermos flask which keeps the U-tube within these limits for several hours. The iodine liberated from the pentoxide is thus sublimed and driven into a tube containing a solution of potassium iodide in which the free iodine can be titrated and estimated in the usual way. The inventor claims that an analysis can be completed in about five minutes with an accuracy of 0·005 per cent. using 100 c.c. of air, or of 0·0005 per cent. with 1 litre. It is of special value for estimating small quantities of carbon monoxide in mine-air, since 0·2 per cent. is highly dangerous, and even 0·02 per cent. produces after a time unpleasant effects. As the quality of compressed oxygen supplied in cylinders is important in life-saving operations in mines, Mr. Graham has introduced a simple piece of apparatus for determining the amount of oxygen by absorbing a known volume in alkaline pyrogallol. Both pieces of apparatus can be purchased from Messrs. Reynolds and Branson, Ltd., Leeds.

IN order to obviate the use of the high voltages required in wireless telegraphy when a triode tube is operated from a direct-current supply by means of a mechanical "chopper" which periodically breaks the supply circuit, Mr. L. M. Hull, of the Bureau of Standards at Washington, has used with great success an alternating supply from a 2-kw. machine giving 500 cycles per second at 150 volts, and a short account of his method and results is given in the Journal of the Washington Academy of Sciences for June 4. The sending key is in the alternator circuit, and the

filament current and plate potential are both provided by means of transformers. The author finds that, operated in this way, the triode tube gives results which compare favourably with those obtained with the usual direct-current method, and that it has the advantage of not requiring a high-voltage generator or battery, while over a limited distance signals may be received with a non-oscillating detector. A more complete account of this work is to appear as a Scientific Paper of the Bureau.

MR. S. J. PEACHEY, lecturer in chemistry at the College of Technology, Manchester, claims to have discovered a process for the cold vulcanisation of rubber. This is applicable not only to rubber in its solid forms, but also to solutions. The final product may be obtained containing no free sulphur. Leather waste, wood-meal, and starch cellulose may be mixed with rubber so as to yield cheap, fully vulcanised products with new properties and great durability. Leather waste and rubber may be converted into a product resembling leather, and at the same time waterproof. No details of the process are given beyond the fact that it employs "two gases which are by-products of several chemical manufacturing processes, and are available at a very low cost." If these claims can be substantiated, it appears that the process should be one of very great technical interest and importance.

FACILITY of manipulation and precision in adjustment are two prime features in X-ray tube stands. They appear to have been carefully considered in the models Mark III. and Mark IV. which we find in Bulletin 255 of Messrs. Watson and Sons, Ltd. In the screen attachment to the latter model there is an arrangement whereby the X-ray tube and the screen move together during vertical examinations. We would suggest that a valuable addition to the illustrations of these models would be the protective devices to be employed with them. It is especially necessary during screening examinations to avoid stray radiation reaching the operator, and the adoption of rigorous protective measures would no doubt become more general if publicity were given to this requirement.

IN the course of an article on Pelton-wheel construction by Mr. Percy Pitman, in *Engineering* for June 25, the author describes the method adopted for improving the jets, which were unsatisfactory in the existing turbine. Experimental nozzles were made in fluid-pressed bronze, and four rustless steel blades, 5 mm. thick, were dovetailed into them so as to lie in axial planes. These blades were ground and highly polished up to a thin knife-edge. A great improvement resulted; the jets were of extraordinary solidity and transparency, the water for about 2 ft. issuing almost like a glass rod. Those interested in the design of Pelton-wheel buckets will find a good deal of useful information in this article; there is but little of practical value in text-books, and the author gives the complete lay-out of the new buckets, and includes copies of the working drawings.

Our Astronomical Column.

AN EASY METHOD OF FINDING LATITUDE.—The *Observatory* for June contains an article by N. Liapin on a method of finding latitude which is interesting and a useful exercise for astronomical students, and requires no other instrument than a watch. The method consists simply in observing the number of seconds between first and last contacts of the sun with the horizon at sunrise or sunset. The formula for solution given by the author is $\cos^2$ latitude $=\sin^2$(sun's decl.)$+4$(sun's radius)^2/(time interval)^2, where the radius and time interval must be expressed in the same units. This formula does not take account of the change of sun's decl. in the interval; a correction for this may readily be made.

Five actual determinations by this method are given, the resulting latitude being 10′ from the truth. While a sea horizon is preferable, any straight and level horizon will serve.

INCREASING THE PHOTOGRAPHIC POWER OF TELESCOPES.—In the Proceedings of the U.S. National Academy of Sciences for March Dr. Shapley describes a method of increasing the photographic power of large reflectors for the purpose of photographing extremely faint objects. The faintest stars at present reached by the 60-in. reflector are of magnitudes 20 to 21, and it is believed that the great Hooker telescope will gain about one magnitude over this. Dr. Shapley is of the opinion that this is bordering on the limiting magnitudes in globular clusters, and if one or two fainter magnitudes were available for study, some most important information might be obtained with regard to several questions of stellar and galactic evolution. The method employed is quite simple, consisting essentially in shortening the effective focal length of the telescope by means of a short focus lens placed between the mirror and the plate. The brightness of the image is thus increased, though, of course, a reduction of scale is inevitable. This, however, is immaterial in many sidereal problems. A trial series of exposures with different intensifiers seems to have yielded satisfactory results, and questions relating to globular clusters, the limits of the galactic system, and similar problems appear to be more hopeful of solution.

A NEW SPECTROPYRHELIOMETER AND SOLAR MEASUREMENTS MADE WITH IT.—In No. 378 of the Scientific Papers of the U.S. Bureau of Standards, recently issued, Messrs. W. W. Coblentz and H. Kahler give an account of a new spectropyrheliometer and measurements of the component radiations from the sun and from a quartz-mercury vapour lamp. The spectropyrheliometer consists of a quartz spectrograph and cylindrical condensing lens placed upon an equatorial mounting, thus eliminating the ultra-violet absorption produced in heliostat mirrors. The paper sums up the data given on the relative components of infra-red, visible, and ultra-violet radiation from the sun and from a quartz-mercury arc lamp, also on the gas-filled tungsten lamp, the iron arc, and the carbon arc. In the first appendix methods are given for excluding ultra-violet light from buildings, one of these being the use of a kind of Venetian blind or louvre of wide slats, painted buff to reflect the light into the building, the buff or red paint absorbing the ultra-violet, thus protecting the contents of the building (balloon hangars, etc.) from photochemical action. The second appendix suggests methods for protecting projection lantern films from the heat of the lamp, and a simple method put forward is to provide the water-cell with windows of Corning "heat-absorbing" glass, which is very opaque to infra-red radiation.

British Association.

SUBJECTS FOR DISCUSSION AT THE CARDIFF MEETING.

THE sectional programmes for the British Association meeting at Cardiff, August 24–28, are now taking shape, and some of the principal scientific subjects which will be discussed may be indicated. The Mathematical and Physical Section, under the presidency of Prof. A. S. Eddington, will be concerned with the Einstein theory, and will receive a paper on the shift of the Fraunhofer lines with reference to that theory. The Section will also discuss the examination of materials by X-rays, the origin of spectra, terrestrial magnetism, auroræ, solar disturbance, and various phenomena of the upper atmosphere. The Geological Section will, as usual, pay attention to local geology, and will also, in joint session with the Sections of Zoology and Botany, discuss Mendelism and palæontology with reference to the Mendelian interpretation of gradual changes, especially when new characters appear late in the individual life-cycle. The Zoological Section will also consider the need for the scientific investigation of the ocean and of fisheries—a subject in which not only the president of the Section (Prof. J. Stanley Gardiner), but also Dr. W. A. Herdman, president of the Association and professor of oceanography at Liverpool University, are leading authorities.

The president of the Geographical Section, Mr. J. McFarlane, will deal in his address with geography and nationality as factors in the formation of the new Europe; the Section will also discuss the distribution of population in South Wales, the new Ordnance Survey maps, the place of geography in a reformed classical course, and various problems connected with Abyssinia, Algeria, Tunisia, Asia Minor, Finland, and other lands. The Engineering Section is expecting papers from Sir Arthur Duckham on the use of coal and from Mr. S. F. Edge on farm tractors, and will also deal with a number of metallurgical and mechanical topics. The Anthropological Section will consider several subjects of Welsh interest, including Welsh ethnology, the Roman sites at Caerwent and Abergele, "hill-top" camps, especially in North Cardiganshire, and Welsh folk-music; in this Section also, among other speakers, Prof. Flinders Petrie is expected to give an account of recent work in Egypt. The Physiological Section, jointly with its sub-section of Psychology, will deal with the subject of psychological medicine in the United States, while the Section will also consider the place of physiology in education, and will receive from Prof. A. D. Waller a demonstration of the "emotive response" of the human subject. The erection of psychology into the subject of a separate section will be brought forward.

The Sections of Physiology and Botany jointly will discuss biochemistry and systematic relationship. The Botanical Section, in addition to other joint meetings, will join that of Agriculture in dealing with soil and plant survey work. In the Educational Section the report of a committee will be received upon training in citizenship, in connection with which Bishop Welldon, Sir R. Baden-Powell, and Lady Shaw are expected to speak. The Section, among other subjects, will discuss the relation of schools to life, post-graduate international education, and the relation of universities, public schools, training colleges, and higher technical schools to a national system. In connection with the last discussion it is hoped to receive a communication on universities from the Right Hon. H. A. L. Fisher. A number of papers of psychological and educational interest will be received in joint session with the sub-section of Psychology. The Agricultural Section will have before it a number of practical subjects concerned with crops and livestock.

In addition to general excursions, several Sections, including those of Geology, Geography, Engineering, Anthropology, Botany, and Education, will visit sites, works, or institutions in Cardiff and the neighbourhood appropriate to their various interests.

The subjects of the evening discourses given at general meetings will be "A Grain of Wheat from the Field to the Table," by Sir Daniel Hall, of the Board of Agriculture, and "Some Requirements of Modern Aircraft," by Sir Richard Glazebrook, lately director of the National Physical Laboratory.

Museums Association Annual Conference.

THE thirty-first annual conference of the Museums Association was held in Winchester on July 6–8, under the presidency of Sir Martin Conway, Director-General of the Imperial War Museum. There were present about a hundred delegates from the various museums and art galleries of Great Britain and Ireland, while Colonial and foreign institutions were represented by Mr. Fitzroy Carrington, from the Boston Museum of Fine Arts; Mr. E. C. Chubb, from Durban Museum; and Dr. G. Johansson Karlin, from the Kulturhistoriska Museet, Lund.

The meeting marked an epoch in the history of the association, since it partook of the nature of a joint conference with the Museums Association of France, which was represented by Prof. Louis Roule, of the Paris Museum, and Dr. Loir, secretary of the French Museums Association.

In his presidential address Sir Martin Conway gave an account of the formation of the Imperial War Museum temporarily housed in the Crystal Palace. He explained how the difficulties of the collection and transport of specimens are being met, and dealt with some of the problems of their storage, especially in the case of war kinematograph films the preservation of which at present is both difficult and expensive. Owing to the vast mass of material collected and the large size of many of the exhibits, the president pointed out that their permanent home must of necessity be spacious. He suggested that no more fitting war memorial could be raised than a stately museum on the Surrey bank of the Thames near the proposed site of the new Charing Cross bridge. Here the thousands of specimens connected with and illustrating the war period could be housed, and with them a complete Roll of Honour, with biographical notes, of every man and woman of the Empire who had fallen in the great struggle.

Mr. E. N. Fallaize read a paper of great interest and utility to museum curators on "Suggestions for the Classification of the Subject-matter of Anthropology." In consideration of the vast field covered by this subject, he pointed out the necessity for the formation of a definite plan for its study, suggesting a broad classification of the subject into two heads, one dealing with man as an organism and the other treating him as a rational being reacting to his environment. For the first, a study of man's structure and the functions of his organs is needed, including a study of the abnormal, both physical and mental. Having thus established a type, the second heading falls naturally into two groups: ethnology, a study of man in space, and what may be termed palæanthropology, a study of man in time. In addition, man's nature as shown in the development and employment of specifically human faculties should be studied, not chronologically, but in a logical sequence

leading from primitive gratification of the senses to man's relation to the unseen.

One of the outstanding problems which a museum curator has to face is that of the lighting of his building, and a paper given by Mr. Hurst Seeger on "The Lighting of Museums and Art Galleries" was particularly instructive on this point. He dealt especially with the question of reflection in the glass of pictures and museum-cases, and pointed out those principles of construction whereby such reflections could be avoided.

Mr. Lowe explained the Public Libraries Act of 1919, stating that, in his opinion, it gave their charter to the museums and art galleries of this country.

A discussion as to the desirability of a diploma for museum curators was opened by Dr. Hoyle, who was of opinion that without some recognised diploma the status of curators could not be assured. In the course of the discussion Mr. Bailey outlined a scheme suggested by Sir Cecil Harcourt-Smith for the training of museum curators at the Victoria and Albert Museum.

A paper on the museum and art gallery of Baroda, dealing particularly with the difficulty of preserving pictures in hot climates, was read by Mr. Dibden.

Mr. M. J. Rendall, Headmaster of Winchester College, gave a paper, illustrated by lantern-slides, on the teaching of art in local museums, emphasising the part played in such teaching by good lantern-slides. He demonstrated the vast difference made by the quality of the slides used, and explained how and where the best slides could be obtained.

Dr. A. Loir gave an account of the formation of an Association of Curators of French Museums, and suggested a joint committee of English and French curators for international co-operation. Papers were read on "The Winchester City and Westgate Museum," by Mr. Hooley; "The Winchester College Museum," by the Rev. S. A. McDowall; "Selection of Pictures for Municipal Art Galleries," by Mr. Howarth; "Biography of the Comte de Lacépède," by Prof. Louis Roule; "The Child and the Mummy," by Mr. T. Peart; and "Suggestions for a Bureau of Exchange through the Medium of the *Museums Journal*," by Mr. Allchin.

A full account of all papers and discussions will be published in the September issue of the *Museums Journal*.

The University of Edinburgh.

NEW SCIENCE BUILDINGS.

THE foundation-stone of the new chemical laboratories of the University of Edinburgh, the first of what will be known in future as the "King's Buildings" of the University, was laid on July 6 by the King, who was accompanied by the Queen and Princess Mary. These buildings are to be erected as separate blocks on a site of 115 acres acquired by the University in November, 1919, mainly for the use of the scientific departments. They are situated on the southern outskirts of the city, near the Royal Observatory on Blackford Hill, and are about two miles distant from the Old College. Thousands of spectators assembled, notwithstanding the drenching rain which fell before and throughout the ceremony.

The general lay-out of the chemical laboratories was planned by Prof. James Walker, who has worked in collaboration with Mr. A. F. Balfour Paul, the architect of the building. The building is rectangular in plan, having a frontage of 220 ft. and a depth of 320 ft. Three corridors, one central and one on each side, run backwards through the whole length, and are connected by a cross-corridor in the front portion. This arrangement permits of indefinite extension by increasing the depth of the building. Between the central corridor and the side corridors are situated the main laboratories with their stores- and service-rooms, as well as the lecture department. Each main laboratory (of which there are five) measures 70 ft. by 45 ft., and receives north light from a saw-tooth roof. Smaller rooms used in conjunction with the main laboratories are situated across the outer corridors, and are lit from the side. The whole building is of one story, except the frontage block and the front part of the east and west wings, which are two stories in height. In these will be housed administration, library, special laboratories, and research-rooms. When complete the department will provide places for about four hundred students working simultaneously. It is estimated that the total cost of the chemical laboratories with fittings and equipment will be approximately 250,000*l*.

His Majesty, in replying to the address of the Vice-Chancellor, Sir Alfred Ewing, expressed the hope that generous donors would be found able and willing to complete the plan of extension which had been sketched with so bold a hand. At the conclusion of the ceremony of laying the foundation-stone the degree of LL.D. was conferred on the Queen.

Lessons from the Smithsonian.

THE report of the secretary of the Smithsonian Institution for the year ending June 30, 1919, is, as always, full of interest, and it differs from similar reports issued in this country in that the points of interest are clearly brought out and not left to be deduced by the reader from masses of undigested detail. The institution controls the work of the National Museum, the Bureau of American Ethnology, the International Exchange Service, the National Zoological Park, the Astrophysical Observatory, and the United States contributions to the International Catalogue of Scientific Literature. The Astrophysical Observatory seems a little out of the picture, but the association of the other bodies tends to co-operation and the prevention of overlap.

The National Museum itself embraces every form of museum activity and combines subjects which in London are distributed among the two sections of the British Museum, the Victoria and Albert Museum, the Science Museum, the Museum of Practical Geology, the National Galleries of Art, and several other collections. The Washington people are as well satisfied with their system as we (to judge from perennial complaint) are dissatisfied with ours. The single administration, it is claimed, "not only ensures greater economy in management, but permits of a more logical classification and arrangement, the elimination of duplication, and a consequent reduction in the relative amount of space required."

Those in this country who are advocating the co-ordination of our museums and allied establishments under a single board would be well advised to study the conditions in Washington. The most obvious danger of such a system is too great rigidity and unnecessary red-tape. It is, however, clear that such an objection does not apply to the Smithsonian Institution. The constitution of the various bodies permits of far more flexibility and enterprise than we are accustomed to in some, at any rate, of the similar bodies in this country. This, it seems to us, is because the Smithsonian is not a Department of State run by politicians or clerks without experience of the varied

activities which they have to direct, but is, from Secretary Walcott downwards, managed by men who have received their training in the field or the laboratory or the museum; men who are familiar with the needs and difficulties of their assistants; men who combine high ideals with a clear appreciation of what is practicable, and so carry out a consistent policy.

A feature of the National Museum, as of other American museums, is the large amount of exploration undertaken. An expedition, including collectors and kinematographers, is now at work in Africa. Mrs. Purdy Bacon has bequeathed fifty thousand dollars to establish a travelling scholarship for the study of faunas outside the United States. Many other expeditions are here reported on. But we would chiefly emphasise the policy of sending out the officers of the museum to study and collect. The whole of the geological staff was thus employed during the field-season of 1918, filling gaps in the collections, obtaining specimens needed for public exhibition, and taking photographs to illustrate the explanatory labels. Many of the other departments also had members in the field.

Among other signs of life and growth, the report records the inauguration of popular scientific lectures, and the introduction of a Bill to provide a museum of history and of the arts as a memorial to Theodore Roosevelt. The building would afford much-needed space for the rapidly extending National Gallery of Art.

The Religion and Origin of the Hawaiian People.

THE sixth volume of the Memoirs of the Bishop Museum at Honolulu[1] continues the publication of Judge Fornander's literary collections. The first portion contains two important papers by native writers on the religion of the Hawaians. One, by Kamakau, contributed to the collection by Dr. W. D. Alexander, describes certain ancient ceremonies of which the principal are those connected with the prenatal development of the royal child, the direction of services to the gods, the catching of the fish *opelu*, and the feasts of the year. There are shorter notes on heathen prayers and the ceremonial erection of the *heiau* or god's house. A much longer paper by the Hawaian author, S. N. Haleole, deals with the functions of the *Kahuna*, "the priesthood called the Order of Sorcery." The word in varying forms (*tahuna, tahunga, tauna*) is used throughout the Eastern Pacific to denote persons possessed of varying degrees of wisdom from priesthood to sorcery, but in the west, in Tonga and Samoa, has become entirely secularised, and there (in the form *tufunga*) means nothing more than a carpenter or skilled workman.

The *Kahuna* in Hawaii was properly trained for his office, and gave evidence of his powers by divination from pebbles, clouds, shadows, and dreams, and by his magical effects with the *maunai* or cast-away portions of nail, hair, tooth, or clothing. His services were in request in times of war and threatened evils, for house-building or loss of lands, in courtship and medicine. The omens of agriculture, canoe-making, and fishing, with descriptions of the occupations themselves, are fully described.

The second part of this volume contains Fornander's speculations on the "Source and Migrations of the Polynesian Race." This appears somewhat out of date in the present stage of linguistic study. The author regards India as the original home of the Polynesian people, and supposes that the Polynesian and Aryan language families separated before the latter had developed their inflected form, and that traces of Polynesians are found in the Malay Archipelago. A majority of the immigrants are thought to have passed through Torres Straits to the Loyalty Islands, and thence to Fiji, Samoa, and Tonga. Fornander's so-called evidence is very unsatisfactory. It is based mainly on the casual resemblances of certain Indian words to Polynesian, the Polynesian meanings being read into the Indian word or *vice versa*.

The theory of an Indian origin of Polynesian may be seen to underlie the theories of Macmillan Brown, Percy Smith, Christian, and Churchill, but certainly lacks the support of sound linguistic evidence. According to this view, everything east of India which agrees with modern Polynesian is borrowed from an ancient form of Polynesian speech, though the languages themselves prove that Polynesia has received many of its words from primitive Indonesia, and that not by one migration, from one place at one time, but in several colonisations from various parts of the archipelago at different times.

The final portion of part 2 contains other papers by Fornander on Hawaian tradition, history, and genealogy.

As all the native writings in the first part are in the original Hawaian with translations, they form a considerable body of text which will be useful to the student of the language, quite apart from their value in the exposition of Hawaian religion. The whole work is very clearly and tastefully printed and a credit to the Museum Press. SIDNEY H. RAY.

Soil Temperatures.[1]

THE paper by Messrs. West, Edlefsen, and Ewing referred to below is an attempt to predict the probable temperature of any hour of any day. If the mean monthly temperatures of any place are known from previous records, it is possible to represent them by a Fourier series of the form

$$T = a + b\cos(\theta - c) + d\cos 2(\theta - e) + f\cos 3(\theta - g) + \ldots$$

where T = temperature at time θ, a = mean annual temperature, b, c, etc. = constants. It is also found for normal days that the temperature at any given hour is a certain percentage of the mean daily temperature, and that this percentage is practically constant irrespective of season. The Fourier series is used to predict the mean daily temperature, which is then multiplied by the appropriate percentage factor to obtain the temperature at the given hour. An arithmetical method, avoiding the use of the Fourier series, is also described. The results are fairly trustworthy for arid regions, but not for humid areas where storms, etc., are frequent.

In Capt. Franklin's third paper on soil temperatures (see "Forecasting Frosts," NATURE, January 1, 1920, p. 450) the variations in the ratio of temperature ranges at the 4-in. depth and the surface, $\left(\frac{R_4}{R_0}\right)$, are studied under a variety of weather conditions. The values vary widely, from 0·19 in a very dry soil to 0·85 during heavy rains. The most common value is about 0·40. The influence of the soil-water on tem-

1 "Determination of Normal Temperatures by Means of the Equation of the Seasonal Temperature Variations, and a Modified Thermograph Record." By F. L. West, N. E. Edlefsen, and S. Ewing. *Journ. Agric. Res.*, vol. xviii. (1920), p. 499.
"The Effect of Weather Changes on Soil Temperatures." By T. B. Franklin. Proc. Roy. Soc. Edinburgh, vol. xl. (1920), p. 56.

perature is very marked. The downward percolation of warm or cold rain from the surface to the 4-in. depth causes rapid changes in temperature, especially in sandy soils, when percolation is rapid. After drainage has ceased a rise in temperature may enable it to begin again, owing to the diminishing viscosity of water with increasing temperature. The formation of a dry surface-mulch reduces the value of $\left(\frac{R_4}{R_0}\right)$ owing to the low conductivity of dry soil. But the actual *temperature* at the 4-in. depth is not greatly reduced by the poor conductivity of the dry soil. This is attributed to the dry surface layers reaching a higher temperature owing to their lessened specific heat, and this counteracts the effect of decreased conductivity. It is shown that a strong dry wind causes the temperature of the surface soil to fall considerably below that of the air. The effect of frost is examined and a formula given for depth of soil frozen in terms of mean surface temperature and duration of frost. A very close relation holds between the date of flowering of coltsfoot and the number of frosts for the two months previous to the date of flowering on open soil not covered with deep snow. It is shown also that strong warm west winds—associated with cyclonic depressions—rapidly raise the temperature of the underground layers of soil in spring. B. A. K.

Control of Insect Pests.

ENGLISH tomato-growers in the Lea Valley are threatened with an annual loss of from 5*l.*–10*l.* per acre unless special remedial measures are adopted against the glasshouse tomato moth, *Polia* (*Hadena*) *oleracea*. L. Lloyd (Monthly Circular of the Lea Valley and District Nurserymen's and Growers' Association, Ltd.) finds that spraying with lead arsenate for the destruction of the pest must be supplemented by trapping the caterpillars and moths and by destruction of the pupæ. The caterpillars can be trapped in old sacks, and ultimately killed by boiling water, while the moths are attracted to wide-mouthed jars containing brown treacle and ale mixed with 1 per cent. of sodium fluoride. Emphasis is laid on the necessity for ascertaining that each control measure is effective.

Several papers have recently been published dealing with the control of various "borers" that infest crop trees. Attempts have been made to control the peach-borer by means of toxic gases derived from poisonous substances distributed on the soil round the base of the trees, E. B. Blakeslee (Bull. 796, U.S.A. Depart. Agric.) finds that the more usual toxic agents, viz. carbon bisulphide, carbon tetrachloride, sodium cyanide, and naphthalene, are all unsuitable for various reasons, but that para-dichlorobenzene offers distinct possibilities for the purpose. The surface crust about the collar of the tree is broken, the required dose of poison (about 1 oz. per tree from 6–15 years old) distributed evenly about the trunk in a band 1–2 in. wide, and a covering of earth applied and moulded up. It is claimed that by this method 94 per cent. of the larvæ can be destroyed.

Much damage is wrought in the United States by the apple-tree borer, which usually takes two or three years to pass through its life-cycle. It is difficult to attack the larvæ by means of poisonous sprays, and mechanical devices are necessarily resorted to. F. S. Brooks (Farmers' Bull. 675, U.S.A. Depart. Agric.) maintains that the most effective method of control is the old-fashioned practice of "worming" with a knife and a piece of wire, but recommends the use of carbon bisulphide when the burrows are obstructed and the larvæ cannot be reached by the wire. Egg-laying can be prevented by a thick coat of paint applied to the bark of the tree, or by means of wrappings of cloth or newspapers applied close enough to exclude the adult female from the bark. The beetle can be killed by spraying the trees with arsenate of lead, as by this means their food is poisoned, but it is doubtful if this is profitable as a general rule.

A most comprehensive account of the toon shoot and fruit borer (*Hypsipyla robusta*, Moore) is given by C. F. C. Beeson in the *Indian Forest Records* (vol. vii., part vii.). The stages of the insect, its life-history and habits, and studies of its seasonal history are fully described, and from the information thus gained the best methods of control are elucidated. The toon borer passes through five generations in the year; the first is spent in the flower, the second in the developing fruits, and the last three in the young shoots of the current season. The effect of this habit is that the first and second broods cause great injury to the seed crop, and in bad years may hinder seed-formation entirely, whilst the three later broods may completely nullify the season's growth in young trees, and, in any case, they cause great delay in the development of the saplings. It is often of little use to make young plantations in the neighbourhood of old toon trees which are infested with the borer. The young trees are subject to attack from their second or third year onward, but may be somewhat protected by banding the trees breast-high with sacking, and removing and destroying at intervals all the larvæ and cocoons found inside the sack-bands. After the fruits are ripe it is advisable to cut out and burn all shoots that are attacked, and in bad cases a second pruning should be made during the cold weather.

Scientific and Systematic Pomology.[1]

IT may be taken as a sign of the development of research in fruit culture in this country, and of the interest which has been aroused in connection therewith among growers of fruit and progressive horticulturists generally, that the well-known firm of nurserymen, Messrs. George Bunyard and Co., Ltd., of Maidstone, has considered the time ripe for the issue of a new quarterly journal devoted exclusively to pomology. The editor, Mr. E. A. Bunyard, a member of the firm named, is recognised both as a practical grower of wide experience and as one of the foremost authorities on systematic pomology and pomological literature. Under his guidance the *Journal of Pomology* should without difficulty establish itself as a publication of scientific value, meeting the needs of a branch of horticulture which has advanced with rapid strides in its importance for the country economically and physiologically since the day when the late Mr. W. E. Gladstone advised farmers to grow fruit for jam production as a remedy for agricultural depression, and is at present none too well catered for in this respect.

The contents of the first two numbers may appear to suggest that there is scarcely occasion yet for a periodical intended primarily to serve for scientific and systematic pomology in this country, some of the more important articles being reprints or abridgments of papers previously published in other journals. Such articles, however, as those by Miss Sutton on self-sterility in plums, cherries, and apples, and by Brooks and Bailey on silver-leaf disease, are of a

[1] *The Journal of Pomology.* Edited by Edward A. Bunyard. Vol. i. Nos. 1 and 2. (Maidstone: Geo. Bunyard and Co., Ltd.) Published Quarterly. Single Nos. 3*s.* 6*d.*; Annual Subscription 10*s.*

degree of interest to pomologists which justifies reproduction in a journal more likely to come under their notice than those in which they originally appeared. It is improbable, moreover, that with research bearing on fruit culture in active progress at such centres as Woburn, Long Ashton, and East Malling, as well as at Cambridge and the John Innes Institution at Merton, there will be any dearth of material on the scientific side for future numbers.

In addition to the articles mentioned, others of particular interest which have already appeared in the journal are those on "Black Currant Varieties," by R. G. Hatton; "Seedling Apples," by the editor and Edward Laxton; "Insect Visitors to Fruit Blossom," by C. H. Hooper; and "The Recognition of Fruits," by H. E. Durham.

Provided that the policy already adopted of the inclusion of reviews and short summaries of recent pomological research as well as of original papers is maintained, those whose interests are mainly centred on fruit culture should find this journal of much service in keeping them in touch with the advance of knowledge in the subject—a matter which has not been easy hitherto owing to the diversity of the publications in which such work has appeared.

University and Educational Intelligence.

BIRMINGHAM.—At a Degree Congregation held on July 10 the Vice-Chancellor (Sir Gilbert Barling, Bart.) conferred the following degrees:—*Doctor of Science:* Frederick Challenger, Arthur Hubert Cox, Harold Ashley Daynes, and John Leslie Haughton. *Doctor of Medicine:* Gladys Mary Cooksey. *Philosophiae Doctor* (a degree new to this University): William Hulse, Frederick Joseph Meggitt, and Leonard Johnston Wills. *M.Sc. (Official):* William Cramp, Arthur Robert Ling, Gilbert Thomas Morgan, Samuel Walter Johnson Smith, and Richard Henry Yapp. *M.Sc. (Ordinary):* F. H. Clews, H. J. Collins, H. G. Evans, A. E. Goddard, F. B. Jenkins, L. J. Lambourn, E. W. Mason, K. N. Moss, A. H. Naylor, N. A. Nicholls, D. S. Newey, A. J. Nicholson, G. N. Scott, H. J. Thompson, E. Tyler, and W. R. A. Weatherhead. *Master of Surgery:* B. T. Rose.

In addition to these, 107 candidates were admitted to the degree of B.Sc. and 16 to the degree of M.B.

The honorary degree of Master of Music was conferred on Sir Thomas Beecham and Francis Donald Tovey.

BRISTOL.—The resignation of Prof. F. Francis as dean of the faculty of science is announced. Prof. A. M. Tyndall is to succeed him in the office, with Mr. P. Fraser as deputy dean.

Prof. C. Lloyd Morgan, on relinquishing his chair, has been appointed emeritus professor of psychology and ethics.

Dr. C. D. Broad has been appointed to the chair of philosophy.

CAMBRIDGE.—Dr. T. M. Lowry, C.B.E., has been elected professor of physical chemistry in the University. This is a first appointment to a newly created chair.

LIVERPOOL.—Dr. W. Mason has been appointed professor of engineering (strength of materials), Mr. C. O. Bannister professor of metallurgy, and Mr. W. H. Gilmour professor of dental surgery.

LONDON.—The King has been pleased to approve the appointment of Mr. Ernest Barker, fellow and tutor of New College, Oxford, to the office of Principal of King's College in succession to the late Dr. R. M. Burrows.

Applications are invited for the William Julius Mickle fellowship, which is awarded annually to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance medical art or science within the preceding five years and shown conspicuous merit. The fellowship is of the value of at least 200*l.* Applications must reach the Principal Officer of the University by, at latest, the first post on October 1 next.

MANCHESTER.—The King, on the recommendation of the Chancellor and Council of the Duchy of Lancaster, has contributed 100 guineas to the appeal fund.

The Manchester correspondent of the *Times* announces that Mr. Maxwell Garnett, Principal of the College of Technology, has resigned, and is asking to be relieved of his duties at the end of the summer vacation. He adds:—"There has for some time past been acute controversy between the Principal and the Education Committee regarding the former's policy of raising the educational status of the college, which constitutes the Department of Technology in Manchester University. The Education Committee recently decided to limit the number of degree students and to admit a certain number of senior technical-school boys as whole-time students. In communicating this decision to candidates for admission to the degree courses, Mr. Garnett suggested the possibility of its reversal by the City Council. The Education Committee published its censure of this letter, and both the policy of the committee, which was represented in the debate as an emergency policy for a single year, and the censure were endorsed by the City Council last week." Under Mr. Garnett's guidance the educational work of the college has developed greatly, the number of matriculated students being now more than six times greater than it was when he became Principal eight years ago. The demand for graduates from the college is far greater than the supply, and there has been a ready response to the appeal for funds for the purpose of extending its highest work.

MR. W. M. CUMMING, hitherto of the British Dyestuffs Corporation, Ltd., has been appointed senior lecturer in organic chemistry at the Royal Technical College, Glasgow.

Two Frecheville research fellowships, each of the yearly value of 300*l.*, tenable for one year, and possibly for a second year, are being offered by the Imperial College of Science and Technology, South Kensington. The fellowships are intended to aid in carrying out any investigation or research connected with mining, mining geology, metallurgy, or the technology of oil considered by the selection committee to be of sufficient use or promise. Applications, in writing, giving particulars of the proposed investigations of candidates, should be made to the Secretary of the College by, at latest, August 31 next.

THE following bequests, among others, were made by the late Mr. T. W. Backhouse, whose death was reported in NATURE of May 13 (p. 335):—50*l.* to the British Association; 700*l.* to his trustees upon trust, to apply the same as they in their absolute discretion may consider expedient towards the carrying on of the scientific calculations based upon observations and notes made by him in astronomy, meteorology, or other branches of science, and towards the publica-

tion of them, any sum remaining over being given to the British Association; and all his astronomical journals and drawings of Jupiter and Mars to the British Astronomical Association. His trustees are to complete and publish the star maps for tracing meteor paths now in process of completion under the care and charge of Sir William Peck, of The Observatory, Edinburgh.

A SUMMER meeting of the Association of Technical Institutions will be held at Cambridge on Friday and Saturday, July 23–24. The proceedings will commence on the Friday at 10 a.m., when the president, the Marquess of Crewe, will take the chair. Papers will be read on Friday morning by Principal J. C. Maxwell Garnett on a national system of education and by Principal C. Coles on the necessity for close co-operation between technical colleges and the universities. On Saturday morning Principal C. L. Eclair-Heath will read a paper on the relations which should exist between the day continuation schools and the central technical college, and Principal L. Small one on adult education in relation to the work of technical schools. Resolutions dealing with adult education will be submitted at the conclusion of the reading of Principal Small's paper.

WE are notified by the Board of Education that the removal of the main offices of the Board from the Victoria and Albert Museum, South Kensington, to King Charles Street, Whitehall, is in progress, and will, it is hoped, be completed by the end of the present month. On and after July 26 the official address of the Board will be Whitehall, S.W.1. It is requested that only urgent communications shall be sent until after July 24, and that these shall be marked "Urgent" on the outside wrapper. The Medical Branch of the Board is at Cleveland House, 19 St. James's Square, S.W.1. The Pensions Branch is at the Science Museum, Imperial Institute Road, South Kensington, S.W.7. The Examinations Section of the Board is housed at 49 Cromwell Road, South Kensington, S.W.7. The office of Special Inquiries and Reports and the Library will remain for the present at the Victoria and Albert Museum. Visitors whose business solely concerns these branches should call at the addresses given above.

THE activity of the scientific society of a school may be taken as a measure of the interest aroused in scientific subjects and a sign of progressive teaching. Clifton College occupies a high position, judged by this standard, and its scientific society, founded so long ago as 1869, continues to foster the inborn aptitude of many young people for observation and experiment. We have before us a list of exhibits at a conversazione given by the society on July 8, and we do not hesitate to say that the demonstrations, apparatus, specimens, and collections shown would do credit to any scientific society. The demonstrations included wireless telegraphy and telephony, the artificial formation of clouds, the fixation of nitrogen, the fractional distillation of petrol from crude petroleum, and other subjects, and the exhibits illustrated many interesting facts and phenomena of biological and physical science. The conversazione was held to show to parents and friends the work and resources of the scientific society, and we are sure that the company must have been impressed by what was displayed. Clifton College is renowned among the public schools for its attention to science, and the recent conversazione shows that it is able to maintain the high place gained for it by men like Wilson, Shenstone, Worthington, and Rintoul.

Societies and Academies.

LONDON.

Royal Society, June 24.—Sir J. J. Thomson, president, in the chair.—Sir Ray **Lankester**: Some rostro-carinate flint implements and allied forms. A series of rostro-carinate flint implements is described and figured in this paper from various localities, including one from the Lower Palæolithic gravel of the valley of the Oise (France). It is shown that the form exhibited by the "Norwich test specimen," with ventral plane, dorsal plane or platform, anterior rostrum, with dorsal carina or keel, is modified in some of the specimens here figured by the "flaking away" of the ventral plane and by the hook-like curvature of the rostrum. A large Sub-Crag example is described, in which only one of the characteristic features of the type, namely, the great ventral plane, is retained, the implement serving as a very efficient "jack-plane." The evidence of the manufacture of these implements by a series of humanly directed blows is indicated by the illustrative drawings.—Lord **Rayleigh**: A re-examination of the light scattered by gases in respect of polarisation. I.: Experiments on the common gases. Re-determinations are given of the relative intensity of the two polarisations in the light scattered at right angles by pure gases. The paper is chiefly concerned with developing accurate experimental methods. The values obtained are as follows:

Gas	H_2	N_2	Air	O_2	CO_2	N_2O
Intensity of weak component polarisation ... (Strong component = 100.)	4·51	4·74	5·68	10·1	12·4	16·1

—A. **Mallock**: Note on the influence of temperature on the rigidity of metals. The experiments here described were carried out at the Davy Faraday Laboratory as a continuation of a somewhat similar set on the temperature-variations of Young's modulus (see Proc. R.S., A, vol. xcv.). The method adopted in the present series depended on the determination of the periods of a torsion balance the restitutive couple of which was given by the rigidity of a specimen of the metal tested at various temperatures. The coefficients of temperature-variation found for rigidity agreed with those for Young's modulus in so far that in both cases the variation diminished as the melting point of the metal increased. The chief value, however, of the present experiments was in showing that the natural plasticity or internal friction of metals (which leads to what has sometimes been called hysteresis) was even more affected by temperature than were the coefficients of elasticity, and that the value of "rigidity" obtained from the observed periods was very appreciably affected by the variation of plasticity. For this reason the numerical results are not given in the paper, but the method of experiment is described and the nature of the errors introduced by the change of plasticity stated.—E. F. **Armstrong** and T. P. **Hilditch**: A study of catalytic actions at solid surfaces. V.: The rate of change conditioned by a nickel catalyst and its bearing on the law of mass-action. The hydrogenation of selected simple organic compounds containing one ethylenic linkage has been studied with reference to the indications of a linear relation between the amount of hydrogenation and time which were observed in the case of mixtures of unsaturated glycerides (part i. of this series). It is now found that this relation, in the case of methyl and ethyl cinnamates, safrol, or anethol (when hydrogenated in the liquid state in presence of nickel at 140° or 180° C.), takes a linear

form for at least 60 per cent., and in most cases 80 to 90 per cent., of the whole action. The interpretation of the mechanism of the action which the authors deduced from the work on unsaturated glycerides thus receives experimental confirmation.—H. **Jeffreys**: Tidal friction in shallow seas. In a recent paper G. I. Taylor has shown that the friction of the tidal currents in the Irish Sea over the bottom causes enough dissipation of energy to account for about one-fiftieth of the known empirical secular acceleration of the moon. This suggests that other and larger shallow areas within strong tidal currents will contribute a still greater amount to the dissipation of energy, and in the present paper the chief shallow seas of the earth are treated separately. The greatest dissipation is found to take place in the Bering Sea, the Yellow Sea, and the Strait of Malacca. Altogether, enough is found to account for about 80 per cent. of the secular acceleration, leaving a balance to be explained by currents in fjords and along the open coast.—Prof. J. C. **McLennan**, J. F. T. **Young**, and H. J. C. **Ireton**: Arc spectra *in vacuo* and spark spectra in helium of various elements. (1) The vacuum arc spectra of antimony, bismuth, calcium, magnesium, silver, and copper, and the spark spectra in helium of antimony, bismuth, aluminium, cadmium, lead, magnesium, thallium, and tin, have been investigated in the region below $\lambda = 1850$ Å.U. (2) The measurements of the arc spectra of antimony, bismuth, calcium, and selenium, and the spark spectra of antimony and lead, appear to be the first recorded for these elements in this region. (3) The work with the vacuum grating spectrograph has resulted in the extension of the vacuum arc spectrum of copper to about $\lambda = 1216$ Å.U.—Prof. J. C. **McLennan** and A. C. **Lewis**: Spark spectra of various elements in helium in the extreme ultra-violet. In this investigation the spark spectra in helium of the elements silicon, tellurium, molybdenum, and zirconium have been determined for the spectral region between $\lambda = 1900$ Å.U. and $\lambda = 1600$ Å.U.—K. H. **Kingdon**: Low-voltage ionisation phenomena in mercury vapour. (1) By the use of a magnetic field experimental proof has been given that when mercury-vapour atoms are bombarded with electrons possessing volt-velocities greater than 4·9, the atoms may be ionised by these collisions. (2) An attempt has been made to explain the experimental results of Davis and Goucher on the basis of the results obtained. (3) Arguments are presented for showing that the production of ions in mercury vapour at this voltage is not so definitely at variance with the Bohr theory as might at first be thought. (4) The experiments go to show that the low-voltage ionisation is not due to ionisation by successive impacts, but that perhaps, in order that a 4·9-volt collision should produce ionisation, the velocity of the impinging electron must bear some definite orientation with regard to the orbit of the electron which is to be ejected from the atom.—Sir George **Greenhill**: Electrification of an insulated lens and allied problems treated by the stream function.—C. **Chree**: Simultaneous values of magnetic declination at different British stations. A comparison is made of corresponding diurnal variations of magnetic declination at Eskdalemuir and Kew observatories. Mean monthly, daily, and hourly values of declination at Eskdalemuir, Stonyhurst, Falmouth, and Kew are compared. The results are also given of the measurements of a large number of irregular declination changes at the several stations. It is found that the differences between different stations increase with the amount of magnetic disturbance, and that if accurate information is desired as to magnetic declination anywhere in the field, observations taken on disturbed days should not be relied on. It is thus important that observatory records should be consulted before the results of field observations are accepted. A number of results are obtained as to the relative amplitudes of irregular declination changes at the several observatories.—J. **Mercer**: Symmetrisable functions and their expansion in terms of biorthogonal functions. The purpose of this communication is to announce certain results relative to the expansion of a symmetrisable function $\kappa(s, t)$ in terms of a complete system of fundamental functions corresponding to $\kappa(s, t)$, regarded as the kernel of a linear integral equation. An expansion of the function of positive type by which $\kappa(s, t)$ is symmetrisable is obtained and applied in two important cases.—W. F. **Sheppard**: Reduction of error by linear compounding. The paper deals with the general problem of improving an observed quantity which contains an unknown error by adding to it a linear compound (linear function) of other observed quantities, called auxiliaries, the coefficients in the added portion being chosen so as to make the mean square of error of the whole a minimum. This is a generalisation of the special problem of finding the improved value when the auxiliaries are the differences of sufficiently high order of a set of quantities. The treatment of the problem is simplified by a brief statement of general theorems, and by a theory of conjugate sets of quantities. The object is to arrive at formulæ suitable for numerical calculation.—G. B. **Jeffery**: Plane stress and plane strain in bipolar co-ordinates. The solution is given for a flat, elastic plate bounded by two circles when under stresses applied over its boundaries. Curvilinear co-ordinates are employed, for which the co-ordinate curves form a double set of orthogonal coaxial circles. Important particular cases are: (1) A circular plate with an eccentric circular hole; (2) a semi-infinite plate bounded by a straight edge with a circular hole; and (3) an infinite plate containing two circular holes. The differential equation of the stress function is solved for these co-ordinates, the stress function is obtained for given arbitrary stresses applied over the boundaries, and expressions are deduced for the stresses and displacements produced at any point of the plate.—R. O. **Street**: The tidal motion in the Irish Sea: Its currents and its energy. Certain general relations are obtained from the Laplacian dynamical theory connecting the form of the tidal wave and the magnitude of the surface current on a sea of limited extent rotating with the earth. In continuation of a former paper, these are applied to the recorded data for the Irish Sea, and the agreement is found to be fairly satisfactory. A second approximation to the hydrodynamical problem for a rotating tidal basin is then effected, and by means of the relations thus obtained the mean rates of transfer of water and of energy across certain vertical sections placed transverse to the direction of the flood-stream in the Irish Sea are computed from the existing hydrographical data. The results show that there is a residual flow of water northwards through this region of such magnitude that the Irish Sea would empty itself through the North Channel about three times a year, while the tidal flow of energy from all causes which takes place into this area is at the mean rate of about 6×10^{17} ergs per second. The result of this estimate of the flow of energy into the area is in general agreement with an independent one made recently by Mr. G. I. Taylor (Phil. Trans., A, vol. ccxx., 1919, pp. 1–33). If we could assume that this energy is all dissipated, the result would be about 250 times the viscous dissipation calculated directly by the writer in a previous paper (Roy. Soc. Proc., A,

vol. xciii., 1917, pp. 348–59), on the assumption of smooth laminar tidal motion throughout the region. —W. G. **Palmer**: The catalytic activity of copper. Part i. Simple apparatus is described for the measurements by chronograph records of the reaction velocities at different temperatures of a typical catalytic action—that of the dehydrogenation of alcohol by copper. Details are given of the methods used in preparing a reproducible contact material. After oxidation and reduction a second time the copper showed an activity of unchanged value. It is shown that copper prepared electrolytically is quite inactive as a catalyst, in spite of great variation in the conditions of its deposition. Copper reduced from its oxide was active at temperatures above 200° C., but this activity depended on the temperature at which the metal was reduced from its oxide.—S. **Barratt**: The origin of the "cyanogen" bands. (1) Observations have been made of the spectra of the flames of a number of gases containing carbon, hydrogen, nitrogen, and oxygen. (2) The cyanogen bands are strongly developed in the coal-gas-nitrous oxide flame. (3) Evidence has been obtained that they are entirely absent from the hydrogen-nitrous oxide flame if all traces of carbon are excluded, and it appears to follow that the presence of carbon is essential to their production. (4) The appearance of the cyanogen bands is, under appropriate conditions, a more delicate test for carbon than that of any of the other bands associated with that element. On the other hand, this spectrum is not necessarily developed when both carbon and nitrogen are present. (5) The conclusion of Grotrian and Runge that the cyanogen spectrum is to be attributed to nitrogen is shown to rest on assumptions which are not confirmed in the present investigation. (6) The cyanogen spectrum provides a very delicate test for the presence of compounds of nitrogen when admitted in the form of a gas to hydrocarbon flames burning in air, since elementary nitrogen does not appear in ordinary circumstances to be effective in producing the cyanogen bands in such flames. (7) The intensity of the cyanogen bands when carbon compounds are admitted to the hydrogen-nitrous oxide flame bears no simple relation to the amount of carbon thus added.—F. **Horton** and Ann C. **Davies**: The effects of electron collisions with atmospheric neon. The critical velocities for electrons in neon were investigated by methods similar to those employed with helium and argon. It was found that neon differed from these gases in showing more than one critical velocity both for radiation and for ionisation, these critical velocities being detected under conditions such as to preclude the possibility of any of them being due to the displacement or removal of a second electron from the atom.—A. G. **Bennett**: The occurrence of diatoms on the skin of whales. With an appendix by E. W. Nelson. The author states that the skin of certain fin whales and blue whales captured in sub-Antarctic waters is discoloured by a superficial film of a buff colour, resembling in tint the coloured bands often observed on floating ice. Whales thus affected are nearly always fat. Microscopic examination showed that this film consists of immense numbers of diatoms. The fat individuals are probably those which have spent some time in the far South, where the supply of whale-food is very abundant during the summer. There is reason to believe that the thin individuals are recent arrivals from warmer water. The skin of these thin specimens appears to be free from any noticeable film of diatoms; their light parts are thus white instead of having the yellow tinge which has given rise to the name "sulphur-bottom" applied by the whalers to whales in which the light parts are yellowish. The cutaneous film of Antarctic "sulphur-bottoms" may be composed of the same diatoms as those which form the coloured bands on ice.—R. W. **Wood**: An extension of the Balmer series of hydrogen and spectroscopic phenomena of very long vacuum tubes.—F. W. **Aston** and T. **Kikuchi**: Moving striations in neon and helium. When an induction-coil spark is passed through a spectrum tube containing neon, and the discharge observed with a rotating mirror, it is seen to consist of bright striations moving from the anode towards the cathode. When first observed the velocity was found to be roughly that of sound in the gas. Further investigations now show that this is only a limiting case of a very complex phenomenon. The velocity is found to decrease with increase of pressure, and also to depend on the bore of the tube. The effect of change of temperature has been investigated, and curves are given showing that at constant volume the effect is much greater than the expansion coefficient. At constant pressure the temperature effect comes in only at high temperatures, when it is probably due to impurities liberated from the tube. Helium is found to give much the same sort of results as neon. Experiments with mercury vapour and other gases are also described. No satisfactory theoretical conclusions have yet been arrived at, and further experiments are in progress.

Geological Society, June 23.—Mr. R. D. Oldham, president, in the chair.—O. **Holtedahl**: The Scandinavian mountain problem. A brief account is given of the history of research regarding the Scandinavian mountain problem, which deals with the superposition of highly metamorphosed, often gneissose, rocks upon slightly altered fossiliferous Cambro-Silurian sediments. From a consideration of the phenomena in the mountain-belt of deformation it is inferred that the age of the displaced materials depends upon the angle of inclination of the thrust-planes and their depth. Though the thrusts have extended downwards for a considerable distance, they have not generally, in the author's opinion, reached below the level of the pre-Cambrian plane of denudation, and no true Archæan rocks could, as a rule, have been tapped. In support of these conclusions some of the tectonic features of two districts are indicated: (1) Finmarken, in Northern Norway, and (2) the southern part of the Sparagmite area near Randsfjord, in South-Central Scandinavia. Brief descriptions are given of the rock-groups in Finmarken and their structural relations. Special attention is directed to the structure of the Alten district, where the main tectonic feature is a highly undulating thrust which does not intersect the pre-Cambrian floor. Regarding the Randsfjord district, the original order of succession of the strata is indicated from the Holmia shale to the close of the overlying Cambro-Silurian sediments. Pressure from the north in Late Silurian time developed imbricate structure in these sediments, but such displacements are not supposed to have affected the pre-Cambrian floor. As investigation proceeds it seems to become increasingly evident (1) that the highly metamorphic sedimentary rocks of the middle and northern parts of the eastern mountain-belt are mainly of earlier Ordovician age, while those west of the Sparagmite region in the south-western mountain district are chiefly of Silurian age, and (2) that the igneous materials associated with these highly metamorphosed sediments are younger intrusive rocks.

Aristotelian Society, July 5.—Prof. Wildon Carr in the chair.—Dr. W. F. **Geikie-Cobb**: Mysticism, true and false. The application of the term "mystic" to current psychic phenomena was unwarranted. True mysticism was an immediate apprehension of the one

as the good rather than the true; it possessed a positive, personal, unquestioning quality which is a necessary feature of all moral valuation, and belonged to the world of the "excessive," and therefore was, *per se*, beyond logic. All attempts to communicate the mystic experience were limited to the use of symbols, and, therefore, by their very nature doomed to partial failure. Those symbols, however, were not selected arbitrarily by the conscious mind, but drawn from the storehouse of the unconscious. Mysticism differs from "extroversion" in that its supreme interest is in the one who is at once another and the ground of the mystic's being. The truth of mysticism is implied in the truth of the self as transcendental, a truth without which the empirical self loses most of its value. But mysticism is not adequately defined as a form of feeling, and what has led to its being so defined is the fact that not thought, but love, is the distinguishing function of all true mystic experience. If an air of unreality surrounds the utterances of mystics, it is only for those who are strangers to love. He who loves eternal beauty holds its transitory appearances as of lesser worth. Dante, for example, at the height of his vision saw love enthroned, and declared that it was love which moved the sun and the other stars. Before this supreme experience of love it would seem that all discursive thought was foredoomed to silence as a worshipper in the outer court of reality.

DUBLIN.

Royal Dublin Society, June 22.—Dr. F. E. Hackett in the chair.—Prof. W. **Brown** and P. **O'Callaghan**: The change in the rigidity of nickel wire with magnetic fields. Transverse magnetic fields, both direct and alternating, have the reverse effect on the rigidity of nickel that direct or alternating longitudinal magnetic fields have; that is, for the former there is an increase, and for the latter a decrease.—Prof. G. H. **Carpenter**: Injurious insects observed in Ireland during the years 1916–17–18. The paper contains records of injury to apple fruitlets by capsid bugs, as recently noticed in England, and also by beech weevils (*Orchestes fagi*), as observed by Theobald in Devonshire in 1912. There are also accounts of the feeding of *Ptinus tectus* in stores of casein and in carpets.—A. G. G. **Leonard** and Agnes **Browne**: Some derivatives of nitrotoluidine (4-nitro-2-amido-1-methylbenzene). The following compounds obtained by the diazotisation of nitrotoluidine [$NH_2 : Me : NO_2 = 1 : 2 : 5$] and suitable coupling have been described: Nitromethylphenylazo-β-naphthol, bright red needles, m. p. 204° C.; nitromethylbenzenediazoamino-*o*-toluene, yellow needles, m. p. 133° C.; nitromethylbenzenediazoamino-*p*-toluene, yellow hexagonal plates, m. p. 131° C.; nitromethylaminobenzene-*p*-sulphonic acid, yellow amorphous substance, m. p. 129° C.; methylnitrodiazoamino-*p*-nitrobenzene, yellow amorphous powder, m. p. 118° C.; and 2-methyl-5-nitro-2′:4′-dihydroxyazobenzene, yellow amorphous powder, m. p. 234° C.—The late Prof. **McClelland** and the Rev. H. V. **Gill**: An investigation into the causes of the self-ignition of ether-air mixtures. When a mixture of ether and air is allowed to expand suddenly into an evacuated tube 3 ft. long and of about 3 in. diameter, it is found to ignite. This ignition is often followed by an explosion which may shatter the tube. The authors describe experiments made to determine the temperatures at different parts of the tube when pure air is used instead of the mixture. A thermo-couple was employed. The increase of temperature following on the inrush of air was found to be a maximum near the closed end of the tube, and to decrease in positions further from the end. The length of the tube has an important effect on the rise of temperature. In the case of a tube 3 ft. long the temperature reached was 193° C. From results arrived at by other methods it appears that this temperature is sufficient to cause the ignition of ether-air mixtures. Theoretical considerations were dwelt on. It is proposed to investigate further certain points of interest connected with this effect.

PARIS.

Academy of Sciences, June 28.—M. Henri Deslandres in the chair.—L. **De Launay**: The course of the Coal Measures in the Central Massif and at its edges. An attempt to deduce some general considerations upon which experimental borings can be placed in the Paris basin.—L. **Maquenne** and E. **Demoussy**: A case favourable to the action of copper on vegetation. A study of the influence of traces of copper salts on the water-culture of lettuce, peas, and wheat.—Em. **Bourquelot** and H. **Hérissey**: The presence in the melilot and woodruff of glucosides furnishing coumarin under the hydrolysing action of emulsin. The fresh plants (*Melilotus officinalis*), extracted with boiling water, gave a solution containing traces only of free coumarin, but the same liquid after treatment with dilute sulphuric acid gave crystals of coumarin on distillation, proving that the coumarin was combined, probably as a glucoside. The plant was shown to contain an enzyme also capable of hydrolysing the glucoside. Similar results were obtained with *Asperula odorata*.—A. **Righi**: Relativity and a scheme for a decisive experiment.—Ch. Ed. **Guillaume**: Values of the expansions of standard nickel-steels. In the preparation of nickel-steels certain amounts of manganese and carbon are necessarily present. For the standard of reference a nickel-steel containing 0·4 per cent. manganese and 0·1 per cent. carbon has been chosen, and the effects of varying amounts of these elements upon the expansion have been based on this as a type. The results are condensed in two curves representing the values of the two coefficients, α_{20} and β_{20}, of the equation of expansion.—G. J. **Rémoundos**: The modulus and zeroes of analytical functions.—J. **Chazy**: The course of the movement in the problem of three bodies when the time increases indefinitely.—E. **Belot**: The origin of solar and stellar heat.—A. **Véronnet**: The temperature of formation of a star in an indefinite homogeneous nebula.—M. **Gouineau**: Verification of the thermo-electricity of liquid mercury. C. Benedicks has recently proved experimentally the existence of a new thermo-electric effect produced in a homogeneous metallic circuit by an asymmetrical distribution of temperatures. The results verify and complete those of M. Benedicks.—A. **Sellerio**: The analysis of three galvanomagnetic effects. Confirmation of a new effect.—M. **Audant**: Contribution to the study of the critical state of ethyl ether. Studies on the variations of the critical temperatures with the tube-filling and on the critical opalescence.—M. **Pauthenier**: The ratio of the absolute retardations in the Kerr phenomenon for different wave-lengths in the case of nitrobenzene. Application of the method of instantaneous charges to carbon bisulphide. The ratio of the absolute retardations in both carbon bisulphide and nitrobenzene is −2 if the times of charge are sufficiently short.—E. **Damour**: The application value (*valeur d'usage*) of combustibles. This value is inversely proportional to the weights of two combustibles required to produce the same thermal effect in a given furnace. Since the efficiency depends on the nature of the fuel, the application value is not measured by the calorific value alone. The temperature of combustion is an important factor in determining the price of a fuel.—R. **Dubrisay**: The application of a new method of physico-chemical analysis to the study of double salts. The method is based on

the measurement of miscibility temperatures with phenol. The miscibility temperatures of certain pairs of salts follow very nearly an additive rule; other salts show marked deviations, and for these the existence of double salts in solution appears probable.—MM. **Lespieau** and **Bourguel**: The production of true acetylene hydrocarbons starting from epidibromhydrin. Compounds of the type $CH_2:CBr\cdot CH_2R$ are readily obtained by the interaction of α-epidibromhydrin and a magnesium alkyl derivative, and from these by three simple reactions good yields of substituted acetylenes, $HC:C\cdot CH_2R$, are produced. Full details of the preparation of normal pentine (n-propylacetylene) by this method are given.—E. **Chaput**: Remarks on the *rôle* of dislocations in the tectonic of the Côte d'Or.—P. **Bonnet**: The movements of the seas at the limit of the Permian and the Trias in the geosynclinals of Eurasia.—G. M. **Stanoievitch**: The aeroplane and hail. Suggestions for the prevention of hailstorms by aeroplanes.—M. **Nobécourt**: The anatomical structure of the tubercles of the Ophrydeæ.—G. **Mangenot**: The evolution of the chromatophores and the chondriome in the Florideæ.—P. **Guérin** and Ch. **Lormand**: The plasmolytic action of a certain number of vapours.—MM. **Lapicque** and **Brocq-Rousseu**: Marine algæ as food for the horse. An account of an experiment on two horses in full work. The oats in the ration were gradually replaced by seaweed (*Laminaria flexicaulis*), and the horses worked normally for twenty days on food from which oats were absent. Then the horses were put to extra heavy work for three days, still on hay and seaweed, and their condition was as good as that of horses doing the same work on the usual food, hay, straw, and oats.—M. **Gautiez**: The influence of the attitude of the body on respiration.—A. **d'Arsonval**: Remarks on the preceding communication.—J. **Amar**: Attitudes of the body and respiration. Walking on the front of the foot, head thrown back, allows large and deep respirations. Walking on the heels has a contrary effect, generally harmful to the health.—R. **Wurmser**: The action of chlorophyll on radiations of different wave-lengths.—A. L. **Herrera**: The imitation of cells, tissues, cell-division, and the structure of protoplasm with calcium fluosilicate. Confirmation of the researches of MM. Gautier and Clausmann on the biological importance of fluorine. Calcium fluosilicate produced by the double decomposition of an alkaline silicate and potassium bifluoride in the presence of calcium chloride and water, if the diffusion of the solutions is very slow, gives remarkable imitations of the structure of protoplasm, natural cells, and their division. These imitations can be studied, stained, and preserved by the usual histological processes.—C. **Pérez**: A new type of Epicarid, *Rhopalione uromyzon*, sub-abdominal parasite of *Ostracotheres spondyli*.—J. **Dragoiu** and M. **Fauré-Fremiet**: Development of the aerial canals and the histogenesis of the pulmonary epithelium in the sheep.—W. R. **Thompson**: *Cyrillia angustifrons*, parasite of a terrestrial Isopod, *Metaponorthus pruinosus*.—P. **Thomas** and A. **Chabas**: The estimation of tyrosin and the dibasic amino-acids in the proteids of yeast.—A. **Mayer**, H. **Magne**, and L. **Plantefol**: The toxic action of dichloroethyl sulphide.—A. **Besredka**: An attempt at the purification of therapeutic sera.—F. **Ladreyt**: Histological polymorphism of certain epithelial neoplasms and the relations between these inflammatory neoformations to cancerous tumours.

SYDNEY.

Linnean Society of New South Wales, April 28.—Mr. J. J. Fletcher, president, in the chair.—G. H. **Hardy**: Synonyms, notes, and descriptions of Australian flies of the family Asilidæ. As a result of work done since the revision of Australian species of this family by Miss Ricardo in 1912–13, it has become possible to establish the identity of many of the species which were not identified at the time. The present paper deals almost entirely with the genus Neiotamus. Of the forty-seven species usually placed in sub-genera of this genus, twenty are dealt with and placed under twelve species; two additional species are described as new.—F. **Muir**: A new genus of Australian Delphacidæ (Homoptera). Most, if not all, of the described Australian Delphacidæ are from eastern States. Of the fourteen genera recorded as Australian the author considers only one as entogenic. The genus described as new in this paper is from King George's Sound, South-West Australia, and is regarded as entogenic.—Dr. C. P. **Alexander**: An undescribed species of Clytocosmus, Skuse (Tipulidæ, Diptera). The genus Clytocosmus was proposed by Skuse in 1890, and has remained monotypic until now, the type species being *C. Helmsi* from Kosciusko. A second species is here described as new from Ulong, on the Dorrigo tableland.

Aerial Navigation and Meteorology.

METEOROLOGY has been international ever since it became a science. From the first congress of directors of meteorological institutes at Vienna in 1873, meteorologists have been engaged in standardising methods of observation and exposure of instruments, and in devising codes for the transmission of observations by telegraph in order to compress as much valuable information as possible in the small space available for transmission at moderate cost. So the introduction of upper-air data, though strongly recommended by those who wanted to substitute calculation for "rule of thumb," had to fight its way against other useful and more easily accessible information of the older kind. The last international code, fixed at Rome in 1913 after long correspondence and discussion, kept the morning message at four groups of five figures, and allotted only one figure to upper-air data—direction of high cloud—in addition to the customary figure for weather or state of the sky. For the benefit of aerial navigation, the results of pilot-balloon ascents were telegraphed by many European observatories to the central station at Lindenberg. Funds for the telegraphic distribution of these data and of those of soundings of the atmosphere by means of kites or cable balloons were usually lacking.

The great war has changed all this; aerial navigation demanded quick and detailed information, especially about low cloud, visibility, and wind velocity in free air. Many reporting stations were erected and connected to central offices by telephone or wireless. Meteorologists sprang up from the ground, the observational hours were multiplied, and no one considered the cost.

The result lies before us in the form of Annexe G of the Convention for the Regulation of Aerial Navigation,[1] the object of which is to substitute legal regulation for free international co-operation. The prominent features are:—

(1) Regulation of the collection and dissemination of meteorological information—introduction of four observational hours instead of two or three; of short-period (three to four hours) and route forecasts (six hours) on one hand, and of long-period forecasts (two or three days) on the other, besides the normal forecasts (twenty to thirty hours).

(2) Extension of the number of groups in the reports from individual stations to a central office from four to six for all stations, and from four to any number between twelve and forty-four for stations observing upper-air wind, temperature, and humidity.

(3) Introduction of new codes for the new information and several of the customary data.

Annexe G has been discussed at a meeting in London of members of the pre-war International Meteorological Committee, and again at the Conference of Directors of Meteorological Institutes at Paris in October, 1919; but definite resolutions were postponed. We have reason to think, however, that the following remarks express the opinion of a large majority of Continental meteorologists and several of their British colleagues.

There is practically no difference of opinion about the necessity of reorganisation and centralisation of the collection and dissemination of meteorological information. Standard observational hours, quick transmission of the reports to the national centre, exchange of collective reports between centres with a maximum distance of 1500 km. within an hour and a half of the observation, followed by selections from these reports sent out over world-wide ranges by a few high-power wireless stations within three hours of the observation, is a good, but not altogether new, scheme. Its complete realisation will be hampered only by the unsatisfactory state of communication by telegraph or telephone in some countries. The proposed simultaneous transmission of several of the national collective reports may cause the receiving stations to miss part of them; successive transmission may take more time than the convention grants; but these are only technical details: the principle is all right. Differentiation of forecasts also is necessary, but it has to be adapted to local circumstances.

[1] "Air Ministry. Convention portant Réglementation de la Navigation Aérienne (13 Octobre, 1919). Convention for the Regulation of Aerial Navigation (October 13, 1919)." Pp. 48. (London: H.M. Stationery Office, 1920.) Cmd. 670. Price 1s. net.

Appendix III. mentions, in addition to the observations of physical quantities like wind, pressure, temperature, and humidity, no fewer than seven kinds of weather phenomena (fog, clouds, precipitation, visibility, etc.), and only as additional and facultative do we find wind, temperature, and humidity in the upper air, in spite of the fact that knowledge of the latter data is essential for a real prediction of weather phenomena, whereas the most minute description of present weather does not form a guarantee against sudden changes. Some years ago it might have been urged that sufficiently recent upper-air data were not available—we have shown, however, in Holland that the aeroplane is an excellent substitute for the kite or the cable balloon in almost any weather, and hence this excuse is no longer permissible. In this respect Appendix III. almost looks like a step backwards.

Certainly the multitude of codes introduced by European meteorological institutes since the war is a nuisance, but it may be taken as a symptom of the general dislike of the codes prescribed in Appendix IV. These include units, like the millibar, unfamiliar to the majority of Continental meteorologists (unless in purely scientific work), and change codes for the transmission of the usual elements without any real gain for practical purposes, and they do not use sufficient economy with the room available in the telegrams. A few specimens may illustrate this. Wind direction is given in two figures as usual, but in a scale of 1 to 72 instead of 1 to 32; this means that an accuracy of 5° is claimed. Every meteorologist knows that such accuracy is imaginary—the exposure of the anemometer, the turbulence of the winds, etc., cause larger variations with space and time. No fewer than four figures are allotted to past and present weather. The result is that the observer is puzzled as to the number he is to choose out of 50 or 100, five or six numbers applying equally well, or he gets into the habit of reporting some favourite phenomenon—the very slightest degree of haze, for instance. The multitude of phenomena reported makes one lose sight of the distribution of any particular class.

In our view, Appendix IV. is a mistake, and ought to be deleted as soon as possible; it may prevent some States from joining the convention, Article 34 of which allows a minority of one-fourth or even less to prevent any modification of the annexes. General rules ought to be given in the convention, details being left to a competent body like the "Comité Météorologique International," reconstituted at Paris in October, 1919, which certainly is fully aware of the need for ref[illegible] choose the best way to ensur[illegible]

In the meantime, reforms are no[illegible] postponed; the majority of the Continental [illegible]ntries have already their wireless collective rep[illegible], and others will soon follow—special route rep[illegible]ts for flying purposes are being exchanged, for [illegible]ample, between England, France, Belgium, [illegible] Holland. Meteorologists are thankful [illegible]e stimulus which aerial naviga[illegible] to their weather services; they admire the desire for organisation and centralisation apparent in the convention; but they cannot overlook the fact that meteorology has other important applications. Theoretically it might be argued that these may look after themselves; practically it is impossible to maintain an independent system of information, say for agricultural purposes. In following up the historical line, the Comité International will try to serve *all* purposes equally well.

E. VAN EVERDINGEN.

Child Physiology.

The Principles of Ante-Natal and Post-Natal Child Physiology: Pure and Applied. By W. M. Feldman. Pp. xxvii+694+6 plates. (London: Longmans, Green, and Co., 1920.) Price 30s. net.

DR. FELDMAN'S work is a notable addition to the books which deal with physiology. As in them, so in this volume, the reader is impressed by the great change which the past decade has wrought in the content of physiological science, and especially in the predominance of physics, of mathematics, and of chemistry which is so noticeable. Here and there one comes upon pages occupied almost entirely with mathematical formulæ. Dr. Feldman's book has all these characters; but it has also another feature, which is novel: it brings to the study of the physiology of the child (up to puberty) a consideration of the conditions of life which exist before birth, and an evaluation of the effect which the process of birth itself has upon these conditions. It has in this respect and for this reason what one might term a fructifying novelty. It sweeps into the scope of child physiology not only the vital processes of fœtal life, which differ merely in details from those which prevail after birth, but also those of embryonic life, which are so manifestly unlike physiology that we commonly call them "embryology," as if they were something apart; and it travels still further back towards the origins of

things and brings in the physiology of the germ or heredity, which it requires an effort of the mind to associate with physiology at all. With so novel an outlook and so enlarged a sphere, it is impossible that everything should be exact and beyond argument; much must remain for a time uncertain, and theories will abound, and do abound, within the cover of this book. For example, the statement that the normal new-born infant is in a condition resembling acidosis is not by any means secure against attack, as a research by Sehom, made so recently as 1919, shows.

Dr. Feldman does not claim to carry over into pathology the ideas which this widened outlook of physiology suggests, and yet indirectly disease and the abnormal are recognised as lying just below the horizon in almost every part. Thus the peculiarities of the fœtal circulation underlie every statement which one can make regarding congenital heart disease. And the converse is also true, for the fact that the fœtal heart beats before and even at birth in a fœtus possessing neither brain nor spinal cord throws light upon the physiology of cardiac action before birth, and suggests that its rhythm is myogenic, and not neurogenic, in origin. Interesting notions spring up on every page, and the reader can scarcely escape the stimulation to think out for himself their application to all sorts of phenomena. One is well accustomed to apply physiology to the clarification of the diseases of adult tissues and organs; but a certain degree of novelty attaches to the effort to look at the pathological occurrences in the new-born infant in the light supplied by the special conditions of ante-natal physiology. For example, the umbilicus is, so to say, the "one portal" by which all things (food supplies, oxygen for respiration, and the germs of disease and toxic substances) reach the unborn infant—it lives through its umbilicus, and it may die by its umbilicus—and after birth, whilst it is no longer nourished by the navel, it may yet for a time be infected through it, as in cases of septic mischief round the root of the cord stump. Most text-books speak with an uncertain sound regarding the diseases peculiar to the new-born infant—the neonatal maladies, as they are called; it will ere long be found that much which is inexplicable in their characters and causation is made plain by the study of ante-natal physiology as it is affected by the impact of birth-traumatism.

The book is abundantly illustrated and admirably arranged, and the author is particularly happy in his choice of the quotations with which he ushers in each chapter. For instance, what a range of thought along novel lines is brought before the reader's mind by Samuel Butler's paradoxical truth with which the work begins: "Birth . . . is commonly considered as the point at which we begin to live. More truly it is the point at which we leave off knowing how to live." One is tempted to turn away from the thought as, in a sense, mental somersaulting; but if one resists this inclination and looks fairly and wholly at it, one sees that Nature's ante-natal provision for the well-being of the unborn child is as near perfection as can be imagined. The fœtus, so to say, knows how to live. Birth comes as the jolt due to the changing of the gearing, and it is some time before the new-born infant, with all the aid that doctor, nurse, and mother can give him, can be said to be in harmony with his environment.

We should like to follow out other lines of thought suggested by this volume, such as His's dictum: "The ultimate aim of embryology is the mathematical derivation of the adult from the distribution of growth in the germ"; but enough has been said to send the interested reader to the book itself, where he will find fertile fields for the intellect to water and in due season to reap.

J. W. B.

Forest Research.

The Fungal Diseases of the Common Larch. By W. E. Hiley. Pp. xi+204. (Oxford: At the Clarendon Press, 1919.) Price 12s. 6d. net.

THIS volume is the most important contribution to the scientific literature of forestry that has been made for some years. Mr. Hiley was well advised to select the larch as the subject of his first investigation as Research Officer in the School of Forestry in Oxford, for it is in many respects the most important species of tree that is cultivated in this country. Moreover, it is a tree the health of which has given much concern to foresters and others for many years past.

After an introductory chapter on the general relationships of host and parasite, and on the morphology of the larch, Mr. Hiley proceeds to deal with the larch disease, or larch canker in the specific sense of the term. This is due to the attack of a Discomycetous fungus, which is usually known in this country under the name of *Dasyscypha calycina.* The author does well to remind us that M. J. Berkeley was the first to recognise the fungal character of this disease, although the work of Willkomm and of Robert Hartig is more frequently cited. Hartig, followed by Massee, believed that infection could take place only through a wound, and it must be said that there is much observational and experimental evi-

dence in support of this contention. Probably the most interesting section of Mr. Hiley's volume is that in which he supports and elaborates the view that in the great majority of cases the stem of a larch is infected by the mycelium of *D. calycina* which is living saprophytically on the dead branches. This theory is not new, but it has never before been subjected to so critical an examination. It is a matter of common observation that a branch springs from the centre of a canker, and it had generally been assumed that death of the branch followed invasion of the stem. But Mr. Hiley now produces evidence which seems to prove beyond reasonable doubt that the branch has always died before the canker has originated, and, in fact, that the dead branch, serving as food for the fungus living saprophytically, has been the vehicle of infection. Such infection always takes place between the end of one growing season and the beginning of the next, consequently the last wood ring in the centre of a canker spot on a stem is always completely formed.

Another parasite of the larch which receives exhaustive treatment in the volume is *Fomes annosus*, the common cause of heart-rot. Unlike *D. calycina*, it is equally common on other conifers, and in the aggregate does a great deal of damage. The same may be said about *Armillaria mellea*, perhaps the most destructive single fungus species with which the forester has to contend.

The more important leaf and seedling parasites are also reviewed, the volume finishing with an interesting general summary and with a useful bibliography. More than seventy illustrations add greatly to the value of the treatise, which is indispensable alike to the mycologist and the forester.

The Absorption of Light by Organic Compounds.

Etudes de Photochimie. By Dr. Victor Henri. Pp. vii+218. (Paris: Gauthier-Villars et Cie, 1919.)

THIS monograph is the first instalment of a series in which are to be presented the results of several years of work of the author and his collaborators. From 1908 to the outbreak of war Dr. Henri devoted his attention to the experimental study of various chemical aspects of the interaction between radiation and matter, dealing chiefly with the absorption of light in the infra-red and ultra-violet regions, with dispersion in the ultra-violet, with chemical reactions brought about by light, and with certain technical and biological aspects of the subject. In 1915 he went to Russia to help in scientific work in connection with the war, and towards the end of 1917 began to work up the mass of data accumulated in preceding years. Very few of his results had been published separately—papers by Bielecki, Boll, and Wurmser will, however, be familiar to workers in this field.

The present volume essentially contains the results of the author's work on absorption and dispersion, and is of considerable interest. Employing a photographic method, carefully checked, and using a powerful source of ultra-violet light, worked out by himself and giving a continuous spectrum, he was able to measure *quantitatively* the exact form of the absorption curve in the ultra-violet for about 240 organic compounds. As he points out, this represents a very considerable advance, previous work being confined to the mere investigation of the positions of the bands. To these measurements are added a series of determinations of dispersion in the ultra-violet, employing a specially designed apparatus, and a number of absorption measurements in the infra-red. The application of formulæ developed by Helmholtz and Ketteler, Drude, Lorentz, etc., has enabled him to draw conclusions as to the nature of the oscillators responsible for the absorption of light of different wave-lengths, the damping (usually very great) to which such oscillators are subjected, etc.

The more important results are as follows: (*a*) The oscillators absorbing in the infra-red are of molecular size, are atoms or fractions of atoms in the mean ultra-violet, and electrons in the extreme ultra-violet. (*b*) These different oscillator systems are closely bound up with one another, and there exist simple numerical relations between the infra-red frequency due to a chromophore and the ultra-violet frequencies in molecules containing such a chromophore. This, of course, was previously discovered by Baly, to whose work adequate reference is not made by the author. (*c*) By the application of simple rules, the absorption spectrum of a compound can be calculated with considerable accuracy from its constitution and the characteristic infra-red frequencies of the chromophores, two simple constants for each infra-red absorption band being necessary. (*d*) The structure of a molecule is essentially *mobile*. The existence of ultra-violet absorption bands is an index of a labile and reactive state. This, again, is in agreement with Baly's views.

Other more speculative conclusions are perhaps less justified. The experimental work appears to be of a high order, and the other volumes promised will be looked for with interest.

Our Bookshelf.

Bibliography of Industrial Efficiency and Factory Management. (Books, Magazine Articles, etc.) With many Annotations and Indexes of Authors and of Subjects. By H. G. T. Cannons. (Efficiency Books.) Pp. viii+167. (London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1920.) Price 10s. 6d. net.

CAN this country pay the interest on the money borrowed during the war without reducing large sections of the community to poverty? The answer to this question appears to be that only by increasing the annual production by at least as much as corresponds to the necessary increase in taxation can we provide enough for everybody. Industrial efficiency is thus seen to be of vital importance. Employers and employed alike should therefore welcome any book which helps to improve methods of production. It will be generally agreed that our manufacturers have still much to learn in this direction.

Mr. Cannons is to be congratulated on having collected no fewer than 3500 references in this bibliography. It would appear that more attention has been given to the subject in the United States than in Great Britain. For example, in a list of thirty-two periodicals dealing more or less specifically with industrial efficiency and factory management, we notice that twenty-three are published in America.

The bibliography is divided into sixty-four subsections. The titles of a few of these will serve to indicate the scope of the book: "Academic study and teaching," "Principles of industrial efficiency," "Factory and workshop management," "Scientific management applied to special branches of industry," "Fatigue study," "Hours of labour," "Personal factor in scientific management," and "Safety methods."

We wish Mr. Cannons had done more to indicate which among the articles referred to are more likely to be worth careful study. Some help in this direction is, however, given in brief notes of the contents of many of the books and papers indexed.

Aliments Sucrés. Sucres—Miels—Sirops—Confitures—Sucreries—Sucs et Réglisse. Par Dr. E. Roux et Dr. C.-F. Muttelet. Pp. vi+474. Paris and Liége: Ch. Béranger, 1914. Price 12 francs.

THE manual of Drs. Roux and Muttelet on the analysis of foodstuffs of which sugar is an important constituent is naturally of somewhat restricted interest. The first part deals with the general optical and chemical methods of determining sugars and various other substances, such as dyes and antiseptics, used in confectionery. In the second part these methods are applied to the examination of commercial products such as honey, sugar, syrups, and preserves. The French laws and regulations dealing with the subject are given at some length together with extracts from those of other countries.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

British and Foreign Scientific Apparatus.

IT may, perhaps, be useful if I attempt to sum up the conclusions that seem to me to be justified from the somewhat divergent views that have been expressed by those who have written upon this question.

It is satisfactory to find that the makers are keenly desirous of meeting the requirements of the scientific worker. I think I am correct in saying that the majority of these prefer to obtain British rather than foreign goods, even at a somewhat higher price, provided that the quality is sufficiently good. It is here that the difficulty shows itself. It is significant that most of the makers who have written on the matter belong to the optical industry, and it is in this case that the state of affairs appears to be the least to be complained about, except, perhaps, in the smaller accessory apparatus, such as the object-marker referred to by Mr. Dunkerly (NATURE, June 3, p. 425). It is chiefly with regard to glass, porcelain, and chemicals that experience has been unfortunate. There has undoubtedly been improvement, but the impression given is that the makers as a whole have not altogether grasped the necessity of putting some of their best men to the work, and that there has been some carelessness in sending out goods of inferior quality. I have been told of flasks the necks of which drop off on the draining rack. It is natural that the users should be critical, especially when a large expense in time and money may be incurred by the breakage of a beaker in the final stage of a process.

The exhibitions arranged by the British Science Guild in 1918 and 1919 showed that excellent apparatus can be produced, and the difficulty is presumably in the main a matter of price. Glass and porcelain of quite satisfactory quality are being made in this country, and due credit should be given to the makers. The Worcester porcelain works, for example, supply excellent crucibles. At the same time, consumers meet with the experience that a large order cannot be relied upon to be of uniform quality. It is unfortunate, though perhaps unavoidable, that unsatisfactory apparatus was put on the market in the early stages of the supply of British glass, and it was to enable a greater perfection to be attained that I made the suggestion of a subvention (NATURE, May 6, p. 293). It is to be remembered that this is being done through the research associations of the Department of Scientific and Industrial Research, and it is in the direction of more scientific investigations that progress is to be looked for. In this connection, I may direct attention to the statement in the leading article of NATURE for June 24 that the profit of some three or four German dye-making firms in 1919 was more than 3,000,000*l.*, as compared with only 172,000*l.* by the British Dyestuffs Corporation.

The manufacturers want prohibition of import of foreign apparatus, at all events for a time, with the granting of special licences to import. I think it will be generally agreed that this would not meet the case, owing to the difficulty and delay that would necessarily be involved. They do not wish for a tariff, and the only alternative seems to be a grant in some form. When British goods have attained the neces-

sary quality and are then put on the market, it appears that there will not be any great risk of foreign competition in the matter of price. Indeed, according to several correspondents, there is little to be feared at the present time. But opinions are not in agreement.

There should be no objection to "manufacturers' associations," provided that their object is to obtain the advantage of more economical methods of manufacture, as by uniformity of standards and large-scale production, rather than the maintenance of high prices.

The cost of all research work, whether paid for by Government grants or otherwise, is greatly increased by inferior apparatus. At the present prices of materials, a single biochemical preparation may cost 4*l.* or 5*l.* or more. This may be lost by breakage at the final stage. The question naturally arises whether economy would not be effected by allowing free import, even at the cost of subventions to British makers.

With reference to Mr. Watson Baker's statement (NATURE, June 24, p. 518) that there are 12,000 German binoculars in London, I confess that I had chiefly in mind the use of apparatus in teaching and research. The sale for general use certainly raises a difficulty. As to losses incurred by work done for Government Departments during the war, so far as my information goes payment for these did not err on the side of economy. Liability for excess-profit duty surely implies that the profit has been made.

The statement by Mr. C. Baker (NATURE, May 20, p. 356) that capitalists will not put money into the business raises another question. It may well be that British makers do not find it profitable to undertake the supply of fine chemicals and special apparatus used only in small amount, even apart from foreign competition. If so, why not give up the trade to those who make a profit on the sale?

The desire of the British industry for prohibition of import appears to rest chiefly on the fear of competition by Germany. I am not one of those who imagine that because an instrument is of German origin it is necessarily superior to all others. Indeed, I have heard of instruments verified at Charlottenburg being found inaccurate. It would certainly be less obstructive than total prohibition if the restriction applied to German goods only. But there are other considerations to be remembered here, such as the importance of giving an opportunity to that country to restore its credit. However this may be, the large profits of their chemical industries referred to above raise some doubt as to the real cause of the present unsatisfactory conditions in Germany.

The point raised by Mr. Dunkerly that American microscopes and lenses are being sold here, although the rate of exchange is against us, suggests that the source of the trouble is not the low value of the German mark. This view is confirmed by other correspondents. If it is correct, there would be no real gain in a mere prohibition of import. Improvements in modes of manufacture are needed, and we come back again to the necessity for more scientific research.

I note that the British Optical Instrument Manufacturers' Association (NATURE, May 20, p. 355) considers that a tariff might have the result of removing the inducement to improve quality, but I foresee so many difficulties in the way of convincing a Government official that a particular piece of apparatus could not be obtained in England that I am unable to accept the suggestion of import by permit as a satisfactory alternative. If, however, it were possible for every scientific worker to obtain without difficulty a general permit for the import of any apparatus at any time the situation would be different.

There seems to be much doubt as to whether it is really possible to obtain foreign apparatus at a price much lower than the British. Should this be the case, the payment of a subsidy might be considered where there is actual underselling. The test would then become one of quality.

The importance of the subject may, I think, serve as an excuse for this lengthy letter. Scientific workers have every desire to assist the development of the industry, but they feel that they are not justified in wasting time and money where it could be avoided. And if this correspondence has brought out the fact that satisfaction has not yet been given in the matter of quality, especially in the case of certain goods, it will have been of some value. It is possible that users have not sufficiently made known their difficulties to the makers, and have been sometimes content with the purchase of foreign material when further inquiry and discussion might have enabled British goods to be forthcoming. W. M. BAYLISS.

University College, London.

The Separation of the Isotopes of Chlorine.

MR. D. L. CHAPMAN'S argument appears essentially to be similar to that already developed from a quite different point of view by Lindemann (*Phil. Mag.*, 1919, vol. xxxvii., p. 523; vol. xxxviii., p. 173), that because isotopes are (theoretically) separable by physical means, they must also be chemically separable according to thermo-dynamical reasoning. The fact that the particular mode of separation by semi-permeable membranes (assumption (3), NATURE, July 15, p. 611) is highly fanciful need not obscure the nature of the argument. Lindemann's conclusion that, though isotopes cannot be identical chemically, the difference may be reduced to an unmeasurable one of the second order of magnitude by suitable assumptions as to the "Nullpunktenergie," seems to indicate the more hopeful line of advance. The chemical non-separability of isotopes, of which there is an accumulated mass of experimental evidence, seems to call for consequent adjustments in thermo-dynamic theory rather than the reverse.

The following considerations may throw light on the matter. I have stated (NATURE, June 24, p. 516) that, on the assumption of the chemical identity of the isotopes, the distribution given by probability considerations of the two kinds of atoms among the three kinds of molecules is

$$Cl_2 : Cl'_2 : Cl.Cl' :: n^2 : (1-n)^2 : 2n(1-n) \quad . \quad \text{(i)}$$

where n and $(1-n)$ are the fractional proportions of the Cl and Cl' atoms respectively. This leads to the equilibrium condition

$$[Cl_2][Cl'_2] = \tfrac{1}{4}[Cl.Cl']^2 \quad . \quad . \quad . \quad . \quad \text{(ii)}$$

Now if one applies in the conventional manner this result to the reversible reaction

$$Cl_2 + Cl'_2 \rightleftharpoons 2Cl.Cl',$$

denoting by k_1 and k_2 the coefficients of velocity of the direct and the inverse reactions, one gets

$$k_1 n^2(1-n)^2 = k_2\{2n(1-n)\}^2$$

or

$$k_1 = 4k_2.$$

This, to say the least, is unexpected, because if coefficients of velocity of reaction have any physical significance at all, one would expect them to be the same for substances assumed to be chemically identical. The result is clearly due to a loose method of

choosing the concentrations, for if we re-write the reversible reaction

$$Cl_2 + Cl'_2 \rightleftharpoons Cl.Cl' + Cl.Cl'$$

it transpires that we have chosen for the concentration of the resultants, because they are the same, the sum of their individual concentrations, although for the reactants, which also are chemically the same, the individual concentrations have been taken. It is clear that it is the individual concentrations in both cases that have to be taken, and therefore that one-half of the Cl.Cl′ concentration is involved. Then $k_1 = k_2$. So with any reaction of this type involving two molecules, apart from the question of isotopes altogether, the 4 that always appears in the conventional text-book examples is merely a consequence of a loose and physically unjustifiable mode of representing the concentrations. Writers of future text-books might ponder a little over this. If the same change in the choice of the concentrations is made in the thermodynamical argument, the difference of entropies, $R \log_e 4$, reduces apparently to $R \log_e 1 = 0$.

I have now made some progress in the application of probability considerations to the kinetics of the reaction. The distribution already given (i) has reference merely to the manner in which the two kinds of atoms will arrange themselves among the three kinds of molecules, assuming promiscuous combination between the two kinds, the two kinds being identical. But the particular distribution obtained does, I find, depend upon the kind of recombination assumed. As regards the dissociation of the molecules into atoms prior to their recombination, the matter appears straightforward, at least so far as I have got. Thus whether one supposes that in a certain time a certain fraction of collisions, the same on the average for each kind of molecular collision, is fruitful in dissociating the two molecules into four atoms, or one regards the dissociation as monomolecular, as presumably it would be if light were the dissociating agent, one arrives at the same result, that if x, y, and z denote fractional proportions of Cl_2, Cl'_2 and Cl.Cl′ molecules respectively $(x+y+z=1)$, the relative rate of disappearance of each by dissociation is similarly denoted. By equating this rate of disappearance to the rate of formation for the three kinds of molecules, one gets the equilibrium distribution. The distribution given by (i) is got in this way, whether (1) all the atoms of the two kinds recombine promiscuously or (2) the four atoms formed in a single fruitful collision recombine again only among themselves. If a similar limitation be applied to a monomolecular dissociation, obviously the reaction cannot affect the distribution at all, which remains unchanged whatever the initial distribution. But I also found by inadvertently applying the law of promiscuous recombination separately to each of the nine cases that have to be taken into account on the collision view—since there are three types of molecules which may collide with any one of the three types—instead of to the sums of each of the two kinds of atoms produced, that a very extraordinary equilibrium distribution resulted, given by

$$Cl_2 : Cl'_2 : Cl.Cl' :: \tfrac{1}{3}n(1+2n) : \tfrac{1}{3}(3-2n)(1-n) : \tfrac{4}{3}n(1-n),$$

which leads to the curious concentration equation

$$[Cl_2][Cl'_2] = \tfrac{1}{4}\{[Cl.Cl']^2 + [Cl.Cl']\}.$$

This in the case $n=0{\cdot}5$ happens to reduce to Mr. Chapman's relation (i) (NATURE, June 17, p. 487).

The case, of course, has no physical meaning, but it may serve to show that the equilibrium distribution is sensitive to the particular assumptions made as to the type of reaction which occurs. I do not imagine I have exhausted the physical possibilities, but, so far as I can see, my distribution relation (i) covers the physically conceivable cases, and therefore the half, not the whole, concentration of the substance undergoing a bimolecular reaction with itself ought to enter into the equilibrium equation.

FREDERICK SODDY.

Science in Medical Education.

THE discussion at the British Medical Association on July 1 on the place of preliminary science in the medical curriculum seemed to indicate practical unanimity on some points, such as the need for a higher minimum standard of general education, the raising of the minimum age for the registration of medical students to seventeen years, and the necessity for the maintenance of a high standard of instruction in physics, chemistry, and biology. There was no indication of the desire on the part of any one of the speakers to reduce the present standard of requirements in any one of these three fundamental sciences, and several suggestions were put forward for extending the courses of each of them into the later years of medical study.

Particularly welcome to many of the science teachers who were present were the remarks of Dr. Brackenbury, who insisted that a high standard of scientific education was just as necessary for the general practitioner as it is in the case of any specialist, and that consequently, in so far as the preliminary science courses are concerned, there should be no division of the courses into a higher and lower standard for different classes of medical students.

On the question of the relegation of the science courses to the school period of the student's education there were some minor points of difference of opinion, and there is need for further consideration of this matter and for the development of a common plan of action. If by raising the age of registration to seventeen years the school period is increased by an average of one year, there will be time for some school instruction in the fundamental sciences after the student has passed a matriculation examination without science, and there can be no doubt that if this time is profitably used, so that the student gains some knowledge of the elementary facts and principles of the sciences, the courses in the first year of study at the universities can be so modified in form as to bring home to the student much more forcibly than the courses do at present the relation of pure to applied science in medicine. The very prevalent idea that a great deal of time is wasted in the first year at the university in learning science that has no application to medicine arises entirely from the fact that the majority of the students come to the university so ignorant of elementary science and so untrained in scientific thought that the time of the university teachers is wasted in teaching the most elementary principles that could and should be taught at school. It seemed, however, to be the general opinion of those who were present at the meeting that the teaching of chemistry, physics, and biology should not cease at the end of the school period, but be extended into the first year of university study in a form which would be more general as regards principles, and more specialised as regards its application to the medical sciences. The suggestion made by Prof. Lorrain Smith and other speakers, that the teaching of science should be extended into the later years of the medical curriculum so that the links that bind the pure sciences to the medical sciences should be continuously presented to the medical student, does

not seem to me really practical unless the time required for a medical qualification is increased.

The time-table of the later years of medical study is already so overcrowded, there is such urgent demand for more time for pathology, for instruction and practice in the wards, for the study of special medical subjects, and for some course of instruction in psychology, that it is difficult to see how any more lectures on pure science subjects can be squeezed in. It seems to me that the special need of medical education at the present time is a carefully thought out scheme of post-graduate studies, in which the teachers of chemistry, physics, and biology would take part, in all the large medical schools of the country.

Manchester. SYDNEY J. HICKSON.

The Mechanics of the Glacial Anticyclone Illustrated by Experiment.

IN various publications issued during the past decade[1] the present writer has treated the peculiar air circulation which obtains above a continental glacier. A number of well-known writers, among them Sir John Murray and Buchan, had early pointed out that essentially anticyclonic conditions obtained over the Antarctic region as a region, but without reference to any connection with the continental glacier; while the late Admiral Peary was the first to note the dominance of centrifugal surface-currents over the Greenland continental glacier,[2] which important observation was the starting point of the writer's studies.

In all my writings upon the glacial anticyclone I have been at much pains to explain that the domed surface of the ice is essential to the development both of the anticyclone and of the alternating calms and blizzards which record its strophic action. In my "Characteristics of Existing Glaciers" it is stated (p. 149): "It is due to the peculiar shield-like form of this ice-mass that the heavier cooled bottom layer [of air] is able to slide off radially as would a film of oil from a model of similar form. The centrifugal nature of this motion tends to produce a vacuum above the central area of the ice-mass, and the air must be drawn down from the upper layers of the atmosphere in order to supply the void. It is here that is located the 'eye' of the anticyclone." Again (p. 266): "This anticyclonic circulation of the air is not determined in any sense by latitudes, but is the consequence of air refrigeration through contact with the elevated snow-ice dome, thus causing air to slide off in all directions along the steepest gradients."

In my monograph published in the Proceedings of the American Philosophical Society it is stated (p. 188): "It is because the inland-ice masses have a domed surface that they permit the air which is cooled by contact to flow outward centrifugally, and so develop at an ever-accelerating rate a vortex of exceptional strength."

It is, of course, fully realised that a domed surface is not the only one which theoretically might be conceived to produce such an anticyclone, but it is the only one of which we have examples in Nature bringing about such results. Any sort of pyramid would suffice; the essential thing is that the surface should have its convexity upwards rather than downwards. Either over a concave surface or about a flat one the refrigerating engine cannot operate.

With the view of demonstrating the relation of the air circulation above a continental glacier to the ice-dome, I have prepared some simple devices for experimentation. In the first experiment water was used as the fluid medium to represent air in an apparatus (Fig. 1) which consists of a glass tank 12 in. by 6 in. by 6 in., containing at the bottom a copper vessel of semi-elliptical cross-section to represent a portion of the domed surface of the glacier. This copper vessel may be filled from below and quite independent of the tank itself. When used for the experiment the tank itself is filled with distilled water at room-temperature, rendered slightly alkaline by addition of sodium hydroxide. Phenolphthalein is then sprinkled over the surface of the water in the tank. It soon develops a dark-red cloudiness which remains near the surface. When ice-water is introduced into the copper dome the adjacent layer of water is cooled by contact and slides off to either side, thus drawing down the coloured water from the surface so as to simulate the vortex and the outflow of a glacial anticyclone. If Victoria green is used to

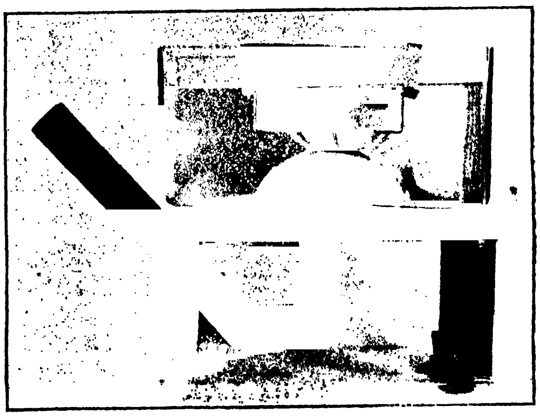

FIG. 1.—A glacial anticyclone simulated in water currents (with use of Victoria green as a colouring dye).

replace phenolphthalein as a dye, its crystals must be supported by a container having a bottom of fine-meshed screen, but in this case ordinary tap-water may be employed, since it is not necessary to render the water alkaline.

A similar experiment may be carried out using air as the circulating medium and smoke as the visible substance which betrays the currents. It is, however, less suited to photographic representation of the circulation, and the device only is therefore represented in Fig. 2. The device consists of a glass jar open at the top, such as is in common use for goldfish; within this jar is a metal dome to represent the domed surface of the glacier. This dome when filled with ice-water at once develops strong anticyclonic circulation of the air in the jar, and the circulation can be made visible if a burning cigarette is supported on a platform near the top of the jar and near its central axis. The jar is covered by a metal plate, the central portion of which is separate and attached to the funnel through which the ice-water is admitted to the dome and on the stem of which is the platform that supports the cigarette. The funnel may almost equally well be dispensed with, and the dome, already filled with ice-water, introduced into the jar with the hand.

2 *Geographical Journal*, vol. xi., 1898, pp. 233–34.

We are here dealing with the constrained motions of falling bodies corresponding to those sliding on inclined planes all joined at their highest points. Such sliding motions are subject to the acceleration of gravity, and hence are slow in starting, but later attain high velocities. Since the falling body is air which is displacing warmer, and [illegible]ter, air-layers, in the case of the glac[illegible] motions are further modified as a result of adiabatic changes, and, since large quantities of moisture are involved, by important transformations of sensible and latent heat. The source of this moisture is believed to be largely the ice-needles of the cirri.

The tendency to produce centrifugal surface-air circulation above the glacier (anticyclonic movement) is promoted by quiet conditions of the atmosphere, since the measure of contact cooling of the surface layer of air over the ice is a direct function of time. The halting of this circulation or the induction of any reverse centripetal movement of the surface air (cyclonic movement) is an inverse function of the time, since it is a direct function of the *distance* the air currents descend vertically during their outward

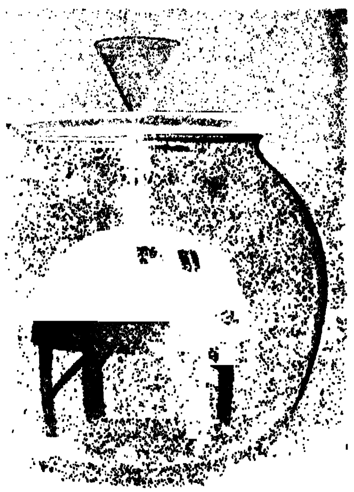

FIG. 2.—Device used to produce anticyclonic circulation in air above a cold dome.

movement. Each of these movements is, however, modified by the transformations of sensible and latent heats of fusion and evaporation of the water brought in in the form of the ice-needles of the cirri.

The beginning of the glacial blizzard, slow by reason of the flattish surface of the ice dome and the acceleration of gravity, is also retarded by the necessity of fusing and vaporising the ice-needles high up in the vortex of the forming anticyclone, which causes *abstraction* of heat and local displacements of air; whereas heat is *evolved* near the end of the blizzard, when fresh snow is precipitated near the glacier surface. Both these transformations of sensible and latent heat will operate so as to add their effect rather than to counteract that due to cooling or to adiabatic effect. They thus tend to cause blizzards to develop gradually and to end suddenly. The halt—the end of the stroke of the refrigerating glacial engine—comes about as soon as the rapid descent of the air carried out by the blizzard has, through its adiabatic effect, quite overcome the surface cooling due largely to the earlier calm. The length of the blizzard, if it precipitates fresh snow, should therefore be adjusted in a measure to the expanse of the glacier surface over which the currents of air must slide before gaining the two miles of descent on the dome, in addition to that which takes place in the "eye" of the anticyclone.

The Diamagnetism of Hydrogen.

THE fact quoted by Dr. Oxley in his letter to NATURE of July 8, that the diamagnetism of hydrogen becomes less as the temperature is raised, seems to be in favour of a kinetic hypothesis of the diamagnetism of that gas rather than against it.

If a magnet starting from rest is made to oscillate it remains paramagnetic until the oscillations on either side of the position of rest become 130°, after which it behaves as a diamagnetic body, the diamagnetism increasing until rotations begin. But once in rotation the diamagnetism *diminishes* as the rotational energy increases; and when this energy is very great the magnet is nearly indifferent to a magnetic field, and it appears to be non-magnetic. If it is allowable to treat temperature as a measure of this energy, then this result means that the diamagnetism should become less as the temperature is raised, and this is what has been observed.

Since the paramagnetism of a rotating magnet is found only for oscillations of less than 130°, the kinetic energy must be comparatively small, and in the case of hydrogen a change from diamagnetism to paramagnetism can be expected to take place only when the temperature is very near to the absolute zero.

Apart from the kinetic hypothesis, the fact that there is any change at all of the diamagnetism of hydrogen with temperature is opposed to the accepted view which regards true diamagnetism as independent of temperature.

Occurrence of Ozone in the Atmosphere.

WITH reference to the lecture of Lord Rayleigh published in NATURE of July 8 on "The Blue Sky and the Optical Properties of Air," the conflicting results obtained by chemical methods in the estimation of atmospheric ozone are recalled. I beg to direct attention to my paper on "The Occurrence of Ozone in the Upper Atmosphere" (Proc. Roy. Soc., 1914, A, vol. xc., p. 204), in which it is shown that a reagent of potassium iodide solution can be made to provide a basis for the distinction of ozone and oxides of nitrogen at high dilutions and enable the approximate estimation of the former. By this method it is shown that, in accordance with the conclusions of Lord Rayleigh, ozone is present in the upper atmosphere, the amount present at an altitude of 10,000 ft. being *of the order of* 5×10^{-8} parts per unit volume. Measurements made with sounding-balloons up to altitudes of 20 km. also showed the presence of definite amounts of ozone, but no detectable increase between 4 km. and 20 km. The view was put forward that this amount of ozone must be taken into account in considering the optical properties of the sky.

An extension of these measurements was made with greater precision at the Mosso Laboratory on Monte Rosa at an altitude of 15,000 ft., where an average proportion of about 1×10^{-6} parts per volume of ozone was found.

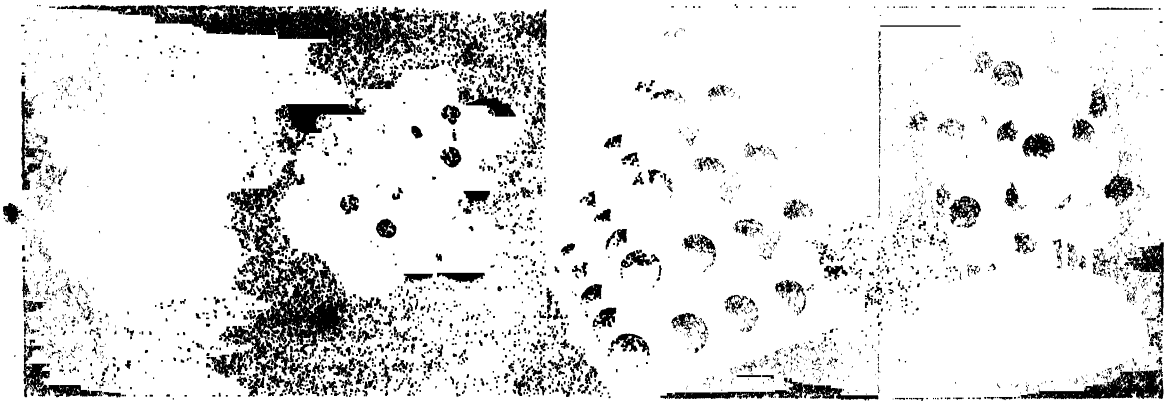
Crystal Structure.[1]

By PROF. W. L. BRAGG.

THE arrangement of the atoms in many of the simpler crystalline forms has now been determined by X-ray analysis. In 1912 Laue published his classical research on the diffraction of X-rays by crystals, and the investigations thus initiated have immensely increased our knowledge of the nature of X-rays, of crystal structure, and of the structure of the atom. Several methods of analysing crystal structure have been used. Laue passed a composite beam of X-rays, consisting of radiations of all wave-lengths over a continuous range, through a thin plate of crystal, and he recorded the diffracted beams by allowing them to fall on a photographic plate. The results he obtained were too complex to admit of ready interpretation, and a simpler method was realised in the X-ray spectrometer devised by W. H. Bragg, in which monochromatic X-rays are reflected from individual crystal faces. In the course of a series of experiments in which the author took part, the structures of a number of crystals such as rock-salt, the diamond, fluor, zincblende, pyrites, and calcite were determined. New fields were opened up by the method of analysis initiated bv Debye and Scherrer, in which a beam of monochromatic X-rays is passed through a mass of finely powdered crystalline material, and the resulting "haloes" recorded photographically. Hull has extended this work to a number of substances unobtainable as large single crystals such as must be used in the X-ray spectrometer. By these methods a wide range of crystal forms has been surveyed.

Some crystalline structures possess symmetry of a high order, examples being potassium chloride and zincblende, models of which are shown in Fig. 1. In such cases as these every atom occupies a symmetrical position in the crystal structure. In potassium chloride each potassium atom is symmetrically surrounded by six chlorine atoms, each chlorine atom by six potassium atoms. The atoms cannot be displaced from their positions without destroying the symmetry of the crystal structure; they are therefore fixed by symmetry alone. Such a crystal is analysed very simply. We have only to choose between various alternative arrangements, each quite determinate, in seeking an explanation of the observed diffraction effects.

When the symmetry does not fix the exact positions of the atoms, the analysis is more difficult. In such cases atoms may occupy any position along some axis or in some plane of the crystal structure, and yet be in accord with the symmetry provided the other atoms of the same kind are given corresponding positions. In the structure of the ruby, Al_2O_3 (Fig. 1), the unit of which the structure is composed consists of a pair of aluminium atoms surrounded symmetrically by three oxygen atoms. The distance apart of the aluminium atoms along the axis joining their centres, and the distance of the oxygen atom from this axis, are both indeterminate in so far as the crystalline symmetry is concerned, and their exact values must be deduced by the X-ray analysis. It is these indeterminate parameters which make a crystalline structure complex.



Potassium chloride, KCl. Calcium carbonate, calcite, $CaCO_3$. Zinc sulphide, zincblende, ZnS. Aluminium oxide, ruby, Al_2O_3.

FIG. 1

The problem is simplified by regarding the atoms in a crystal as a set of spheres packed tightly together. This manner of regarding the structure was proposed in 1907 by Barlow and Pope, who assigned to the sphere representing an atom a volume proportional to its valency, and by packing these spheres together as closely as possible they obtained structures which accounted for crystal forms. We now know the structure of the crystals dealt with by Barlow and Pope,

[1] Discourse delivered at the Royal Institution on Friday, May 28.

and we know that it is in many cases not that predicted by the "valency volume" law. The law can be modified, however, so as to apply to the majority of crystals so far analysed. It may be shown that we can assign a definite diameter to the sphere representing the atom, a diameter characteristic of the element in question. Some atoms appear to occupy a small domain in a crystal structure, others a larger space. By finding the distances between the atomic centres in a number of crystals the diameters represented in Fig. 2 have been calculated. This figure summarises an empirical relation, which states that the distance between neighbouring atomic centres in a crystal structure is equal to the sum of two constants, characteristic of the atoms concerned. We can therefore picture the crystal structure as a set of spheres packed tightly together, just as Barlow and Pope did; but in this case the dimensions of the spheres are those in Fig. 2, not those given by the valency volume law.

arrangements, those of the inert gases, are those in which the outer shell has its full complement of electrons. Such forms are very stable; they are characterised by a weak external field. The chemical properties of the other elements represent their tendency to revert to a more stable electron system.

The crystal of potassium chloride, on this point of view, consists of alternate potassium and chlorine ions. The potassium atom is surrounded by nineteen electrons when electrically neutral. Eighteen of these electrons complete the three electron shells, represented, for instance, by the very stable arrangement of argon. The remaining electron has no place in the stable system, and there is therefore a tendency for the atom to part with it and become a positively charged potassium ion, the nucleus with nineteen elementary charges being surrounded by eighteen electrons. Chlorine similarly tends to gain an electron. The KCl structure may therefore be re-

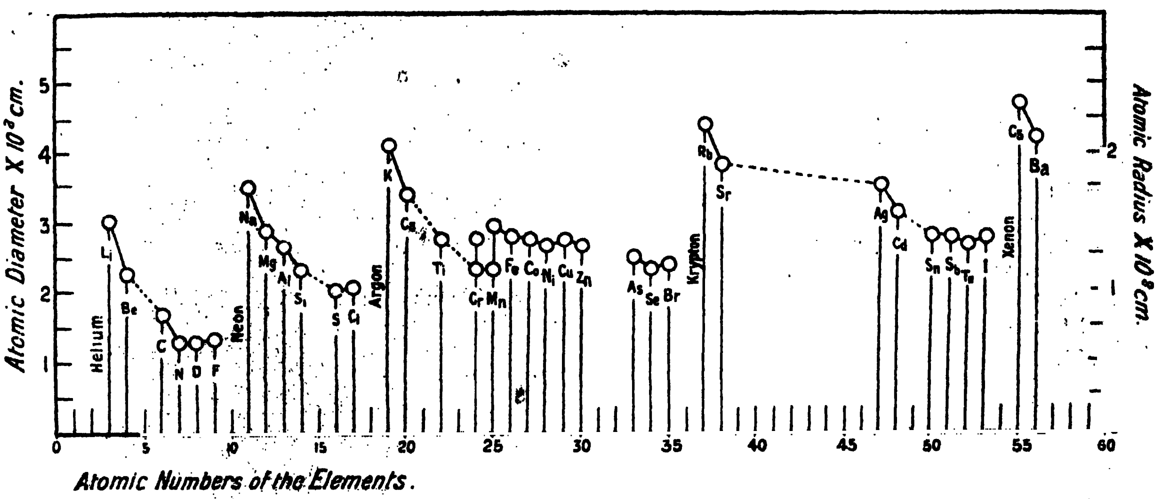


FIG. 2.

The atoms in a crystal are thus packed together as if they were inelastic spheres in contact. This is merely a way of visualising the structure, and must not be interpreted too literally. A ready explanation of the form of the graph in Fig. 2 is afforded by that conception of atomic structure which Stark, Born, Landé, Lewis, and others have helped to build up, and which has recently been so brilliantly summarised in a series of papers by Langmuir. Many independent lines of investigation have led to the conception of the atom as a positive nucleus surrounded by an electron system, in which the electrons are fixed at, or oscillate about, certain definite positions in the atomic structure. This is a view which forms a contrast to the Bohr atomic model, where the electron orbits enclose the atomic nucleus. In the "fixed electron" atom the electrons are arranged in a series of shells surrounding the nucleus, the numbers which complete the successive shells being 2, 8, 8, 18, 18, and 32. Certain

garded as an assemblage of argon shells, with resultant positive and negative charges, which are held together by their charges, and kept apart by some force of repulsion which we must suppose to exist between the outer electron systems. The result is the structure in Fig. 1 where every ion is surrounded symmetrically by the greatest possible number—six—of ions of the opposite sign.

In the case of two electro-negative elements which are chemically combined, both atoms have a smaller number of electrons than corresponds to stability of the outer shell. Stability is attained by their holding pairs of electrons in common. In this way Langmuir has succeeded in the most striking manner in explaining the complicated valency of such elements as nitrogen and phosphorus.

The structure of calcite (Fig. 1) is an example of both types of chemical combination. The calcium atom, represented by the large sphere, is

an ion with a double positive charge, the CO_3 group an ion with a double negative charge. These ions group themselves in the same way in the calcite and potassium chloride structures, as the models show, except that the form of the CO_3 group distorts the cube into a rhombohedron. The electro-negative atoms of carbon and oxygen hold electrons in common, and form a closely knitted group, and from their distance apart we can form an estimate of the dimensions of the outer electron shell; it is the lower limit to which the diameters tend at the end of each period in Fig. 2.

In this an explanation is found of the large diameters assigned to the electro-positive elements, and the small diameters assigned to the electro-negative elements, in Fig. 2. The electro-positive atoms never share electrons with their neighbours; they are therefore isolated in the crystal structure, and appear to occupy a large domain. The electro-negative elements, bound together by common electrons, have to be represented by small spheres.

Comparing two crystals such as sodium fluoride and magnesium oxide, which have identical structures, we see that both may be represented by alternate electron groups of the Neon type. In the case of magnesium oxide the ions carry a charge twice as great as the sodium and fluorine ions, and the consequence is that the MgO structure, though identical in form with the NaF structure, has its dimensions reduced. The side of the elementary cube has a length of 4.22×10^{-8} cm. in the case of MgO, a length of 4.78×10^{-8} cm. in the case of NaF.

In diamond every carbon atom is surrounded symmetrically by four other carbon atoms arranged at the corners of a tetrahedron. The carbon atom has four electrons in its outer shell, and, in order to complete the number eight required for stability, it shares a pair of electrons with each neighbouring atom. The whole crystal is thus one continuous molecule, and the great hardness and density receive a simple explanation.

A crystal of an electro-positive element cannot be bound together by common electrons. Here we must suppose that the crystal consists of ions and electrons, the ions representing the stable electron systems, and the electrons being present in sufficient numbers to make the whole assemblage electrically neutral. From the fact that all crystals of electro-positive elements are conductors of electricity we deduce that the electrons have no fixed place in the system; they move under the influence of an electromotive force.

It has been possible only to indicate the manner in which crystal structure helps to elucidate the structure of the atom, and many generalisations have been made to which there are exceptions. It is hoped that this discussion will show the interest of the study of crystals. In a crystal there are countless atomic groupings oriented with perfect regularity. Individually their effect is too small to observe, but by illuminating the crystal with X-rays, the wave-length of which is much less than the distance separating the atoms, we can make use of their concerted effect on the rays to enable us to see into the intimate structure of matter.

Researches on Growth of Plants.[1]

By SIR JAGADIS CHUNDER BOSE, F.R.S.

II.

The General Principle Determining Tropic Movements.

THE movements in plants under the stimuli of the environment—the twining of tendrils, the effect of temperature variation, the action of light inducing movements sometimes towards and at other times away from the stimulus, the diametrically opposite responses of the shoot and the root to the same stimulus of gravity, the night and day positions of organs of plants—present such diversities that it must have appeared hopeless to endeavour to discover any fundamental reaction applicable in all cases. It has, therefore, been customary to assume different sensibilities specially evolved for the advantage of the plant. But teleological argument and the use of descriptive phrases, like positive and negative tropism, offer no real explanation of the phenomena. I propose to describe experimental results from which it will be possible to discover an underlying law which determines the various tropic movements in plants.

Direct Effect of Stimulus.—In the motile pulvinus of Mimosa the excitation caused by stimulus causes a sudden diminution of turgor and contraction of the cells. With regard to this fall of turgor it is not definitely known whether excitation causes a sudden diminution in the osmotic strength of cell sap or increase in the permeability of the ectoplast. The state of excitation in a vegetable tissue may, however, be detected, as I have shown elsewhere, by the following indications: (1) diminution of turgor; (2) contraction and fall of leaf of Mimosa; (3) electromotive change of galvanometric negativity; (4) variation of electric resistance; and (5) retardation of the rate of growth.

Continuity of Physiological Reaction in Growing and Non-growing Organs.

In investigations on the effect of all modes of stimulation, mechanical, electrical, or radia-

[1] Continued from p. 617.

tional, I find that they check growth or bring about an "incipient" contraction; when the intensity of stimulus is increased, the effect culminates in an actual contraction—a result exactly parallel to the contraction of the pulvinus under direct stimulus. This would explain the similarity of tropic movements in pulvinated and growing organs.

Indirect Effect of Stimulus.—A novel result was discovered under indirect stimulation—that is to say, when the stimulus was applied at some distance from the responding area, *i.e.* the pulvinus or the growing region. This caused an increase of turgor, an expansion, an enhancement of the rate of growth, and an erectile movement of the leaf of Mimosa, and an electromotive variation of galvanometric positivity. This effect is specially exhibited in tissues which are semi-conductors of excitation.[2] The contrasted effects of direct and indirect stimulus are given in the following tabular statement:—

TABLE I.—*Direct and Indirect Effects of Stimulus.*

Direct	Indirect
Diminution of turgor, contraction.	Increase of turgor, expansion.
Fall of leaf of Mimosa.	Erection of the leaf.
Diminution of the rate of growth.	Enhancement of the rate of growth.
Galvanometric negativity.	Galvanometric positivity.

In Fig. 4 is given a record which shows in the same specimen (1) the acceleration of growth under indirect, and (2) a retardation of growth under direct, stimulation.

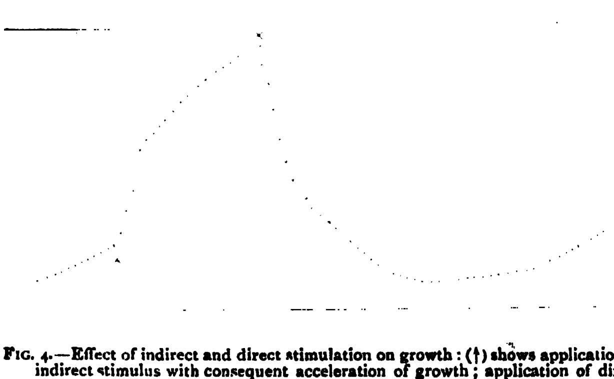

FIG. 4.—Effect of indirect and direct stimulation on growth: (↑) shows application of indirect stimulus with consequent acceleration of growth; application of direct stimulus at (×) induces contraction and subsequent retardation of growth.

We thus arrive at the law of effects of direct and indirect stimulus:—

Direct stimulus induces contraction; indirect stimulus causes the opposite effect of expansion.

The same law applies when stimulus acts on

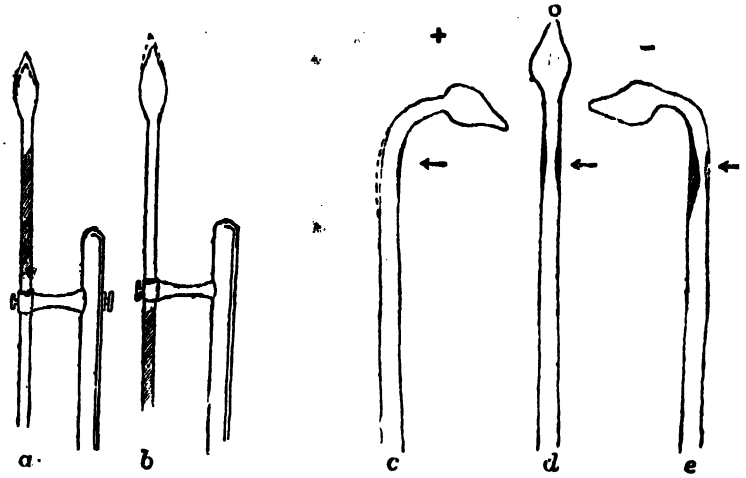

FIG. 5.—Effects of direct and indirect stimulus: *a*, Stimulus applied directly at the growing region inducing retardation of growth or contraction as represented by dotted line (stimulated area in this and in following represented as shaded); *b*, stimulus applied indirectly (at some distance from growing region) gives rise to acceleration of growth and expansion; *c*, stimulus applied at right side of organ causes contraction of that side and expansion of the opposite side, thus giving rise to positive curvature towards stimulus; *d*, excitation transmitted to the opposite side causes neutralisation; *e*, excitation caused by intense stimulation is transmitted across and thus reverses the normal curvature to negative, *i.e.* away from stimulus.

one side of the organ. When stimulus of any kind acts on the right side (Fig. 5*c*) the directly stimulated right side contracts, and the indirectly stimulated opposite, or left side, expands, the result being a *positive* tropic-curvature towards the stimulus. This explains the twining of tendrils and positive heliotropism.

Negative Heliotropism.—When the light is very strong and long continued, the over-excited plant-organs may begin to turn away. How is this effected? My experiments show that the strong excitation percolates into and traverses the organ and provokes contraction on the further side, thus neutralising their former bending (Fig. 5*d*). The organ now places itself at right angles to the light, and this particular reaction has been termed dia-heliotropism. In certain cases the transverse conductivity of the organ is considerable. The result of this is an enhanced excitation and contraction of the further side, while the contraction of the near side is reduced on account of fatigue caused by over-excitation. The organ thus bends away from light or exhibits so-called negative heliotropism (Fig. 5*e*). These effects are accentuated when one side of the organ is more excitable than the other. Thus under the continued action of light the response record shows first a movement towards light, then neutralisation, and finally a movement away from light. In this way a continuity of reaction is demonstrated proving that the assumption of specific positive and negative heliotropic sensibility is unjustified.

That the application of stimulus on the near

[2] "Plant Response," p. 524.

side of the organ induces at first an increase of turgor on the distal side and that this first effect may be neutralised and reversed by transverse conduction of excitation are seen strikingly exhibited in the accompanying record (Fig. 6), where a narrow beam of light was applied at a point of the stem diametrically opposite to the motile leaf which was to serve as the indicator of the induced variation of turgor under the unilateral action of light. That this indirect stimulation caused an enhancement of turgor of the opposite side was soon demonstrated by the erectile movement of the leaf. When the stimulus is moderate and of short duration, the response is only erectile or positive. But when the stimulation is continued the excitatory impulse is conducted to the distal side, giving rise to diminution of turgor, contraction, and the fall of the leaf.

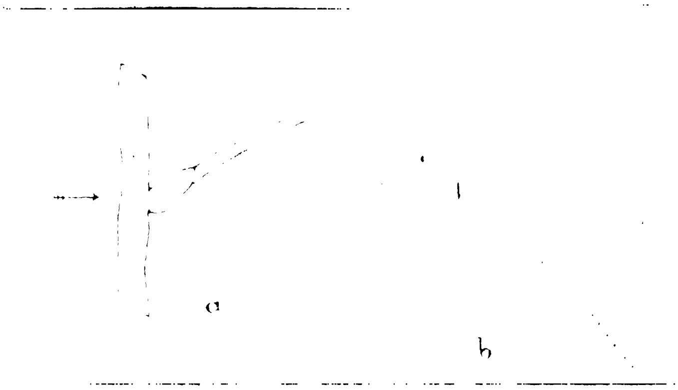

FIG. 6.—Increased turgor due to indirect stimulation inducing erection of Mimosa leaf: *a*, diagram of experiment; *b*, erectile response (shown by down-curve) followed by rapid fall (up-curve) due to transverse conduction of excitation.

TABLE II.—*Showing Responsive Effects Common to Pulvini and Growing Organs under Unilateral Stimulation.*

Effect of direct stimulation on proximal side	Effect of indirect stimulation on distal side
Diminution of turgor.	Increase of turgor.
Contraction and concavity.	Expansion and convexity.
Galvanometric negativity.	Galvanometric positivity.

When stimulus is strong or long-continued, the excitatory effect is conducted to the distal side, neutralising or reversing the first response.

Space does not allow my entering into the question of Nyctitropism, which will be found fully explained in the "Life Movements in Plants," vol. ii.

Geotropism.—No phenomenon of tropic response appears to be so inexplicable as the opposite effects of stimulus of gravity on the root and the shoot. As regards the mechanism of the upcurving of a horizontally laid shoot, it may be due either to the expansion of the lower side or to an active contraction of the other. In order to decide the question I devised the method of geo-electric response whereby the state of excitation (which is attended by contraction) is independently detected by the induced electromotive change of galvanometric negativity. Displacement of the shoot from the vertical to the horizontal position is found to be immediately followed by the clearest electric indication that the upper is the excited side. The electrical response is found to increase as the sine of the angle of inclination. This excitation of the upper side involves its contraction and the resulting geotropic curvature upwards.

Localisation of Geo-perceptive Layer by Means of the Electric Probe.—The new investigation was carried out by means of my electric probe, which consists of an exceedingly fine platinum wire enclosed in a capillary glass tube, the probe being thus electrically insulated except at the extreme tip. When the probe, suitably connected with a galvanometer, is slowly thrust into the stem, so that it enters one side and comes out at the other, the galvanometer deflection shows by its indication the state of irritation of every layer of cells throughout the organ. When the stem is held in a vertical position the probe during its passage shows little or no electric sign of irritation. But when the stem is displaced from the vertical to the horizontal position, the geotropically sensitive layer now perceives the stimulus and becomes the focus of irritation, and the probe on reaching this point gives the maximum deflection of galvanometric negativity. This electric indication of irritation disappears as soon as the geotropic stimulus is removed by restoration of the stem to a vertical position. I was thus able to map out the contour lines of physiological excitation inside a living organ. The geo-perceptive layer was thus localised at the endodermis.

In geotropic response the only anomaly that remained was in regard to the response of the root being opposite to that of the shoot. Every cut portion of the growing region of the shoot responds to the stimulus of gravity by bending upwards. The growing region of the shoot is therefore both sensitive to stimulus and responsive to it. *Hence geotropic stimulation of the shoot is direct.* But this is not the case with the root; here it is the tip of the root which perceives the stimulus, the geotropic bending taking place at some distance from the tip. From the results of electric investigation I find that the root tip becomes directly stimulated, while the responding growing region some distance from it becomes indirectly stimulated. *Hence geotropic stimulus acts indirectly in the responding region of the root.* I have shown that the effects of direct and indirect stimulus on growth are antithetic; it

therefore follows that the responses of shoot and root to the direct and indirect stimulus must be of opposite signs.

The diverse movements of plants are thus explained from the establishment of the general law that direct stimulus induces a contraction and indirect stimulus an expansion.

I have shown, further, the extraordinary similarity of physiological reaction in the plant and animal (Friday evening discourse, Royal Institution, May 29, 1914). The responsive phenomena in plants must thus form an integral part of various problems relating to irritability of all living tissues, and without such study the investigation must in future remain incomplete.

Popular Natural History.[1]

(1) THE best popularisers, after all, are the masters—if they care to try; and Fabre's "Story Book of Science" is a fine illustration. It is very perfect—full of interesting material, vividly written, stimulating both observation and reflection. He tells of ants, aphides, long-lived plants and animals, procession caterpillars, bees, spiders, shells, cotton, paper, silk, clouds, thunder, rain, the sea, and more besides—all as if it were a pleasure to him to talk, and just the very easiest thing in the world. The book must have been fashioned long ago, but so wisely that there is little that requires changing; it was meant for the children of more than a generation ago, and it would be a joy of a reading-book in schools to-day; it was written in French, and it reads as if it had been composed in English. The translator, Mr. A. T. De Mattos, has done his work with great skill. We confess that we should not call Hemerobius a dragon-fly, and there must be something wrong in speaking of the "sharp bones" in the silk-moth's cornea, which Fabre described as a rasper for filing at the silk threads of the cocoon. But these are pin-pricks; the book is past praising, and its pages are very pleasant to read—pleasant both to the inner and the outer eye. We should be having a Fabre centenary soon.

(2) A translation of Fabre's "Story Book of Birds and Beasts" is very welcome. The subjects are for the most part familiar, but the handling of them is masterly in its simplicity, grip, and vividness. Fabre had a way of taking the reader into his confidence, and making a sort of partner of him in his observations. But it is a game that only a big man can play with success. We are introduced to the cock and the hen, the egg and the chicken, the duck and the goose and the pigeon, the cat and the dog, the sheep and the cow, the horse and the donkey, and we get interested in them as if they were novelties. It is high art. The stories should be used in schools.

The book is not without blemishes, of which we venture to give some samples. We do not know what to call the first part of a hen's stomach, but we are sure that it cannot be called "the succenturiate ventricle." The story of the making of the shell of the egg is misleading, and it is not true to say that the hen *must* have carbonate of lime in her food. We are rather staggered by some humming-birds "as small as our large wasps." The account given of "pigeon's milk" is erroneous. It should have been noted that the passenger pigeon, in regard to which Audubon's account is quoted, has now ceased to exist. For the translator's work we have great admiration; but it might have shown wisdom as well as piety to have got an editorial expert to look into points such as we have illustrated. There is no sense in perpetuating mistakes.

(3) Dr. Francis Ward's book is in great part an attempt to take the point of view of the animal under water.

> Seen from below, the surface of the water would appear as an extensive mirror, with the river-bed reflected upon it. Immediately above the observer the reflecting surface is broken by a circular hole or "window." Through the surface of the water, in the area of this "window," the sky and objects immediately overhead have their usual appearance, but in addition surrounding objects above the water level are also seen through the "window" as dwarfed and distorted images, suspended, as it were, in the air above the circumference of the circular hole. A ring of iridescent colours separates the "window" from the surrounding reflecting surface.

Many of Dr. Ward's observations have a direct bearing on the concealment of aquatic animals, and deserve careful attention from naturalists. Let us illustrate. The size of the "window" varies with the depth of the under-water observer; when birds and fishes on the surface slip out of the "window" they cease to be conspicuous (to their enemies below) as silhouettes against the sky. Protection under water may be afforded, as in the case of brown trout, by reflection of the surrounding coloration. White animals, such as a white sea-anemone, take up a position where the revealing top light is cut off. Black-plumaged birds, like the water-hen, become mirrors under the water owing to reflection from the air-bubbles retained in their plumage.

After explaining the sub-aquatic conditions as

(6) "Wonders of Insect Life: Details of the Habits and Structure of Insects." Illustrated by the Camera and the Microscope. By J. H. Crabtree. Pp. viii+211+32 plates. (London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., n.d.) Price 6s. net.
(7) "Just Look! or, How the Children Studied Nature." By L. Beatrice Thompson. Pp. viii+204+58 plates. (London: Gay and Hancock, Ltd., n.d.) Price 5s. net.

regards illumination, the author discusses the life and behaviour of a number of types. In connection with diving birds, he suggests that the "flashes" of reflected light from the moving body may attract fishes. Under the water the back of the Great Northern Diver "simulates a shoal of small shining fish." The inordinate appetite of diving birds is emphasised; thus a small cormorant took from Dr. Ward at one time twenty-seven herrings of average size. It seems to us that the author does not sufficiently appreciate

The otter alarmed. From "Animal Life under Water."

the good these birds do from the fisherman's point of view in destroying species which devour food-fishes. There are two sides to most indictments of birds.

In addition to the contributions to the theory of concealment of water animals from enemies or from booty, the book contains many very interesting natural history sketches—of the seal, the heron, the kingfisher, various kinds of gulls, and, best of all, the otter. Indeed, the story of the otter strikes us as the finest part of the book. We are not sure that a popular book, especially one with a definite and very interesting problem to discuss—animal life under water—is the place for weighing the beneficial and injurious effects of the activities of particular birds. That should be done in a severely scientific and critical way. Dr. Ward describes, for instance, the contents of the stomachs of thirty black-headed gulls, which show that these birds were "certainly not helping the farmer." But it is easy to get expert records of thirty cases which show the reverse. The question is to which side the balance inclines in a particular area and through the year. This entertaining and breezy book is copiously illustrated with very interesting photographs. We appreciate these, but we may hint at the injudiciousness of putting even a diagrammatic penguin into a scene on a Highland loch.

(4) Mr. Hudson's "Birds in Town and Village" is based on "Birds in a Village" (1893), his first book about bird life, but much of it is new. It is a continual delight—a succession of fine pictures—and it is very gratifying that the beautiful text should be so successfully illustrated. Mr. E. J. Detmold's coloured drawings are altogether charming. The time is past for speaking of the author's style, his irresistible enthusiasm, his intimate knowledge of birds, and his passion for them. If more people read his books there would soon be no need for a Plumage (Prohibition) Bill.

"The robin is greatly distinguished in a sober-plumaged company by the vivid tint on his breast. He is like the autumn leaf that catches a ray of sunlight on its surface, and shines conspicuously among russet leaves." "The kingfisher, speeding like an arrow over a field of buttercups so close that they were touching, seemed, with the sunshine full on it, to be entirely of a shining, splendid *green*. . . . Flying so low above the flowery level that the swiftly vibrating wings must have touched the yellow petals, he was like a waif from some far tropical land. The bird was tropical, but I doubt if there exists within the tropics anything to compare with a field of buttercups—such large and unbroken surfaces of the most brilliant colour in nature." But we might as well quote the whole book. The delightful "Birds of a Village," which forms about half the book, is echoed at the end in a story of the birds in a Cornish village, and between the two there are essays on exotic birds for Britain (we confess to regarding introductions with insular prejudice),

moorhens in Hyde Park, the eagle and the canary (concerning cages), chanticleer, and the birds of an old garden. If the birds knew what Mr. Hudson has done for them, they would sing all the year round.

(5) It is difficult to imagine anything more delightful than Mr. Hudson's "Book of a Naturalist," and we wish he had called it vol. i. Why should there not be many volumes, when it is so easy to make one so good? So easy! for all that is necessary is to have (1) an intimate personal experience and a deep understanding of the life and conversation of animals as they live in more or less wild Nature; (2) an artistic or poetic sense which gives Blake's "double vision"; and (3) an ear for words that makes the pages of the book sing. The same subjects are often treated of by many painters, and likewise by many naturalists. Ants and wasps, bats and foxes, moles and earthworms, snakes and toads, pigs and potatoes—these are fair samples of Mr. Hudson's stock in trade; but he is a magician-pedlar, and the familiar things among his wares turn out to have most unexpectedly profound and subtle excellences. Here science and art seem to meet in a deepening of our appreciation of common things, and perhaps this is the biggest service that a man who sees can do to his day and generation.

Mr. Hudson wished to call his book "Diversions of a Naturalist," but Sir Ray Lankester was ahead of him. We do not think he lost much, for what he has given us are really "Appreciations," as Sir Ray Lankester's "diversions" were also. The expert biologists get down to the depths of life in a way that is indispensable and fundamental, but the field-naturalists, among whom Mr. Hudson stands out as Saul among the prophets, get at the heights of life in a way that is indispensable and supreme. What is contributed in these fascinating essays is a wealth of first-hand observations, and to this, of course, there are added the reflections of a highly gifted intelligence. But we submit that there is more—that feeling has a *rôle* in the interpretation of Nature, and that sympathetic insight (through æsthetic emotion at one pole, and sheer sense of kinship at the other) opens up one of the rights-of-way to reality. This is too academic in its phrasing, and unfair to Mr. Hudson, through whose writings sunlight streams and breezes blow; but we mean that this is the book of an expert naturalist and of a man of feeling as well.

(6) The entomologist is always discovering new wonders, and very frequently he has enthusiasm enough to wish to share his pleasure with others. Mr. Crabtree has the entomological enthusiasm right enough, but we are not sure about all his wonders. In the first place he is too much of an anthropomorphist, for he says the study of insect-life "provides a host of examples and illustrations of such noble aims as 'living for a purpose,' 'striving for the best,' 'helping one another,' 'bearing each other's burdens,' and 'sympathy in sorrow.'" He has interesting observations to describe, and he tells his story fairly well; but again there is the false note: he should not speak of his book selecting "representative members of the principal *species*," or of "the Pulex family." It is a pity that an author who seems to have seen a lot of things for himself should write like this: "The numerous family of Lice that is parasitic on certain animals is classed under the common term Hæmotopinus." Why do not publishers see to it, by utilising readily available advice, that this sort of thing is not printed? It is not good business, for it obscures the book's good qualities.

Many people see common insects like the lady-bird, the devil's coach-horse, the earwig, the frog-hopper, the green-fly, the may-fly, and the wasp, and would like to know more about them, especially if they can get the information not too learnedly expressed. Mr. Crabtree's book is well adapted to meet this reasonable demand. It deals pleasantly with about three dozen common insects, and there is a generous supply of photographic illustrations. But, again, Mr. Crabtree's reach too often exceeds his grasp; thus his story of cuckoo-spit is far from correct; we do not like to hear of female Aphides without ovaries, in which "multiplication occurs by the process of gemmation or budding on the individual Aphis." We are staggered by the crane-fly, the limbs of which are merely hooked together, so that a captured part has only to be hooked off; and we do not think that a wise approach to a very difficult problem is made by saying: "It may be said with sincerity that the development of *instinct* in ants is much akin to *reason* in higher mammals." But, forgiving a lapse in biological philosophy, we are pulled up by errors in grammar, for our eyes have fallen on more than one sentence like this: "To the thorax, or chest, is attached the fly's six limbs." Why should a scorpion be referred to as "the dangerous arachnid of the South American forests," and why should an author go out of his way to use an expression like "of that ilk" when he does not know what the words mean? We believe in popular natural history, but it should have a high standard of accuracy, and it should be written in English worthy of the subject. Mr. Crabtree's studies are interesting; they often describe observations; they are certainly instructive; but we are bound to say that there are too many flies in the ointment. And many of these flies are gratuitous.

(7) Miss Thompson tells in a pleasant way of corals and seeds, of the work of water and ice, of springs and seashore animals, and illustrates her talks with very clever drawings. To those who enjoy talks between a somewhat encyclopædic Miss Marshall and a number of children who ask extraordinarily appropriate and searching questions, the book will be welcome; our own impression, based on some experiments, is that neither children nor adults care for the "Sandford and Merton" mode of imparting instruction. The author has a very skilful pencil and a power of simple exposition; we wish she had chosen the direct method.

J. A. T.

Notes.

MR. ALAN A. CAMPBELL SWINTON has been elected chairman of the council of the Royal Society of Arts for the ensuing year.

DR. EDRIDGE-GREEN, C.B.E., has been appointed a special examiner in colour vision and eyesight by the Board of Trade.

THE Civil List Pensions granted during the year ended March 31 are shown in a White Paper just issued, and include the following:—Mrs. Howell, in recognition of her late husband's eminent public service in the Geological Survey of Great Britain, 50*l.*; Miss Juliet Hepworth, in recognition of her late brother's services to meteorology and oceanography, 50*l.*; Mrs. K. Macdonald Goring, in recognition of her husband's services to biometrical science, 85*l.*; and Mrs. Leonard William King, in recognition of her husband's services to Assyrian and Babylonian study, 85*l.*

AT a public meeting held at the Mansion House in October, 1912, the following proposals for commemorating the work of Lord Lister were adopted:—The placing of a memorial in Westminster Abbey, to take the form of a tablet with medallion and inscription; the erection of a monument in a public place in London; and the establishment of an International Lister Memorial Fund for the advancement of surgery, from which either grants in aid of researches bearing on surgery or awards in recognition of distinguished contributions to surgical science should be made, irrespective of nationality. A meeting of the general committee was held in the rooms of the Royal Society on Monday, July 19, to receive and adopt the report of the executive committee appointed in 1912. The chairman, Sir Archibald Geikie, stated that the sums received in respect of subscriptions from the British Empire and foreign countries amounted to 11,846*l.* 5*s.* 10*d.* A memorial tablet, executed by Sir Thomas Brock, was unveiled in Westminster Abbey on November 1, 1915, and steps are being taken for the erection of a monument in a public place in London. In order to carry out the scheme for the establishment of the International Lister Memorial Fund for the Advancement of Surgery, it was resolved that:—(*a*) Out of the general fund a sum of 500*l.*, together with a bronze medal, be awarded every three years, irrespective of nationality, in recognition of distinguished contributions to surgical science, the recipient being required to give an address in London under the auspices of the Royal College of Surgeons of England. (*b*) The award be made by a committee constituted of members nominated by the Royal Society, Royal College of Surgeons of England, Royal College of Surgeons in Ireland, University of Edinburgh, and University of Glasgow. (*c*) Any surplus income of the general fund, after providing for the erection of a monument and defraying administrative expenses, be either devoted to the furtherance of surgical science by means of grants or invested to increase the capital of the fund. The Royal College of Surgeons of England has consented to become the trustees and administrators of the Lister Fund and to carry out its objects, subject to the above provisions of the scheme. The subscription list is still open, and the hon. treasurer of the fund is Sir Watson Cheyne, Bart., to whom donations may be addressed at the Royal Society, Burlington House, London, W.1.

A MARBLE statue to the memory of Wilbur Wright was unveiled on July 17 at Le Mans, where twelve years ago this aviator accomplished a flight of nearly a mile. We learn from the *Times* that the statue is the work of the sculptor Landowski, and typifies the struggle of man to conquer the air. The nude figure of a man is represented as having scaled a rugged mountain peak and as stretching out his arms to the hitherto unconquered element, air. The base of the monument is carved with bas-relief figures of Wilbur and Orville Wright and Léon Bollée, the Frenchman who collaborated in the early experiments.

THE thirty-ninth annual meeting of the Society of Chemical Industry was held at Newcastle-upon-Tyne on July 13–16. The gold medal of the society was presented to M. Paul Kestner, president of the Society of Chemical Industry of France, by Prof. Henry Louis, who read the presidential address of Mr. John Gray. Sir William J. Pope was elected president for the ensuing year. An invitation to hold the next annual general meeting at Montreal was accepted.

A CONGRESS of Philosophy, in which members of the Société Française de Philosophie are taking part, and to which the American Philosophical Association is sending delegates, is to take place at Oxford on September 24–27. Two of the subjects of discussion are likely to be of especial scientific interest: one a symposium on the principle of relativity, to be opened by Prof. Eddington, and the other a discussion to be opened by Dr. Head on disorders of symbolic thinking due to local lesions of the brain. The opening meeting of the congress will be presided over by Lord Haldane, and the inaugural address will be by Prof. Bergson. Arrangements are under the direction of Mr. A. H. Smith, New College, Oxford.

THE Faraday Society and the Physical Society of London are arranging to have a joint symposium and general discussion in October next upon the physics and chemistry of colloids and their bearing on industrial questions. The subject will be introduced by a brief survey of the present position of colloidal physics and chemistry, and there will then be discussion on the following subdivisions of the subject:—Emulsions and emulsification, physical properties of elastic gels, cataphoresis and electro-endosmose, precipitation in disperse systems, glass and pyrosols, and non-aqueous systems. In spite of the importance of colloidal physics and chemistry in many branches of manufacture, and of the interest which the subject has aroused in recent years, much light remains to be thrown on the nature of the manufacturing process in which colloids play a part. It is hoped that the discussion will focus attention on some of these problems, that its result will be to indicate lines of advance and suggest

further researches, and that it will be fruitful not only in helping to a fuller understanding of the laws of the colloidal state, but also in suggesting new applications for colloids in the laboratory and in the works. The exact date and place of meeting and further particulars will be announced later. In the meantime, anyone desirous of using the opportunity of the discussion to bring forward experimental matter or theoretical considerations bearing on the above-mentioned branches of the subject is asked to communicate as soon as possible with the secretary of the joint committee, Mr. F. S. Spiers, 10 Essex Street, London, W.C.2.

A SPECIAL meeting of the Röntgen Society was held on July 15 in the chemical theatre of University College, London, by kind permission of the authorities. The occasion was an address by Dr. W. D. Coolidge, director of the research laboratories of the General Electric Co., of Schenectady. An audience of more than 250 people gathered to hear from the inventor of the X-ray tube which bears his name a detailed account of the processes involved in the manufacture of the Coolidge tube—or rather we should say the Coolidge tubes, for a number of different types of tube, each suitable for different working conditions, are the outcome of the investigations carried out under Dr. Coolidge's direction over a number of years. Dr. Coolidge in his address laid considerable emphasis upon the amount of investigation entailed in the use of tungsten either as a hot filament or as the target of an X-ray tube. The welding of this highly brittle metal and its perfect annealing with copper are technical triumphs, and the details of these processes in their final stages were of very great interest. While the effort is at present being made by the General Electric Co. to standardise radiographic procedure by combining a high-tension outfit which automatically limits the quantity and quality of the X-rays from the tube, it is recognised that no such procedure is possible in radio-therapy at the present day. The limitations imposed upon the production of very short wave-length X-rays are largely technical ones, and we look with confidence to their production in the near future, for both in medical work and in the examination of metals and other materials they are likely to prove of great value. If the production of these more penetrating radiations involve new ideas in the construction of the X-ray tubes, those who heard Dr. Coolidge's address will feel that such considerations will not be allowed to delay what is becoming a seriously felt want.

IN a paper read before the Royal Statistical Society in April (Journal, 1920, vol. lxxxiii., part 3, pp. 1–44), Dr. T. H. C. Stevenson presented the results of an inquiry into the fertility of the various social classes in England and Wales from the middle of the nineteenth century to 1911. Child mortality varies directly and very markedly with the number of children born and the rapidity with which they are born. It also varies with the age of the mother at birth. If allowance is made for the differences of marrying age in different classes, fertility is found to increase downwards throughout the social scale. The difference in fertility between the classes is, broadly speaking, a new phenomenon, for it is small for marriages before 1861, and rapidly increases to a maximum for those of 1891–96. That the decline in the birth-rate is due to the artificial restraint of fertility is indicated by the following features: The gradual spread of the decline throughout society, from above downwards; the exceptionally low fertility of occupied mothers; and the increase in the defect for the higher social classes with increase of duration of marriage up to twenty-five years. The lowest fertility rates are returned for the most purely middle-class occupations —the professions. The comparatively low child mortality of the less fertile classes goes but a small way numerically to compensate for their low fertility. The classes which are least fertile when married are likewise those that marry latest in life. Ante-nuptial conception leads to great under-statement of the number of marriages of less than twelve months' duration. Such under-statement is the rule amongst all classes where the wife's marriage age is under twenty, and becomes less frequent as the wife's age increases. At ages above twenty its frequency varies with the social position, reaching its maximum amongst unskilled labourers.

PROF. E. W. MACBRIDE contributes to the latest number of *Scientia* (vol. xxviii., No. 99, 1920) a trenchant article on "The Method of Evolution." By the "force of heredity," he says, is meant the tendency of the offspring to resemble the parent. It is obvious that in some way this force must be modified as time progresses, otherwise evolution could not take place, and the manner and means of this modification are just what we mean by the phrase "method of evolution." The Darwinian view that large results may be reached by the selection of small individual variations is seriously weakened by "pure line" experiments. The mutationist view of the importance of "sport"-variations exhibiting Mendelian inheritance cannot be accepted as more than an accessory theory, for most mutations are of the nature of "cripples," and utterly unlike the differentiating characters which distinguish allied species. There remains a third alternative: the inheritance of the effects of use and disuse. This is *the* method of evolution, "the dominating influence which has moulded the animal world from simple beginnings into the great fabric of varied life which we see around us." If we ask for evidence of the transmission of somatic modifications, we are referred by Prof. MacBride to the researches of Kammerer. If we submit that opinion is divided as to the validity of these, we are told to repeat the experiments, which is, of course, a fair enough answer. In the meantime, we are invited to consider how bacteria, modified to perform feats in disruptive chemistry of which their ancestors were incapable, hand on their individually acquired new qualities to their abundant progeny. And if we suggest that this is not a test case, since bacteria have no soma and do not multiply by germ-cells, we are told that the distinction between somatoplasm and germplasm is a "Weismannian nightmare." All this points clearly to the need for fresh experiments.

PROF. STEPHENSON's paper "On a Collection of Oligochæta from the Lesser-known Parts of India and from Eastern Persia" (Memoirs Indian Museum, vol. vii.) is very informative. The known Oligochæta, about 150 before 1883, were about 1000 species in 1911. To these Prof. Stephenson adds 24 species and 5 varieties, modestly remarking: "It can scarcely be said, however, that the results of the present investigation include anything of the first order of importance; it is now too late to expect it." One of the new species, *Nais gwaliorensis*, is about one-tenth of an inch long and one-hundredth of an inch broad, yet in an earlier paper the author shows this brevity far outdone by Annandale's *Chaetogaster spongillae*. Among very much larger forms the systematist may note that Prof. Stephenson here makes his *Eutyphoeus Kempi* a synonym of *Eutyphoeus chittagongianus*, Michaelsen, and that author's *bengalensis* a synonym of his species *Waltoni* in the same genus. So lately as 1893 "absence of branchiæ" was included in the definition of the Oligochæta. Now, not only does *Branchiura Sowerbyi*, Beddard, have, as its generic name implies, gills on the tail end, but Prof. Stephenson also finds a species of Branchiodrilus, "a Naid worm with gills remarkably like those of Branchiura, but on the anterior part of the body."

THE twenty-eighth Report, for the year 1919, on the Lancashire Sea-Fisheries Laboratory contains a note by Mr. A. Scott upon a midwinter invasion of the Barrow Channel by an immense swarm of the phosphorescent flagellate Noctiluca and the Ctenophores Pleurobrachia and Beroë. On December 16, 1919, Mr. Scott made one of his routine visits to the sandy mud-flats between tide-marks, and found that the area—500 yards wide and 1000 yards long—between Roa Island and Foulney appeared as if it had been thickly sprinkled with glass marbles. These were the Pleurobrachia, many of them of large size (22 mm. high), and mingled with them were stranded Beroë. At the water's edge was a brick-red, oily-looking zone 6 in. to 12 in. wide, and the water in the creeks was covered by a similar oily layer, which on examination proved to be composed of Noctiluca. Twenty-four hours later the area was again examined, but only one Pleurobrachia was found, and there was no Noctiluca in the plankton. It is quite unusual to find an abundance of Noctiluca and Ctenophores in this area in midwinter. Noctiluca has been abundant on former occasions along the coasts of North Wales and Lancashire, but hitherto only in the period between the beginning of August and the end of September.

THE "Reports for the Year 1919 on the Science Museum and on the Geological Survey and the Museum of Practical Geology" (H.M. Stationery Office, 1920, price 3*d*.) are accompanied by a map showing the grouping of institutions devoted to education and research in the great quadrangle between Cromwell and Prince Consort Roads, South Kensington. The Science Museum has gone into temporary occupation of part of the eastern block of new buildings while this block is being completed, the galleries thus occupied being left in an unfinished state until a second move onward can be made. The arrangement is a testimony to the energetic and necessary expansion of the collections, which now include an aeronautical division. The report on the Museum of Practical Geology refers to the congestion of its collections, which have been largely increased by the groups of materials of economic importance brought together in recent years. There is no reference, however, to any scheme of extended buildings. The publication of maps and memoirs has been maintained at a high level, and it is interesting to note how the public demand shows an enormous and intelligent preference for the "drift" series of colour-printed maps as against those showing the "solid" geology only.

THE Geological Survey of Scotland has issued the fourth of its series of memoirs dealing with the detailed economic geology of the central coalfield of Scotland, the present volume being devoted to Area VI., which forms a block near the centre of the field and includes the districts of Rutherglen, Hamilton, and Wishaw. This is naturally an area of very great economic importance, and comprises some of the most productive portions of the Scottish coalfield. A valuable feature of the publication is the series of sections obtained from borings and sinkings, which have been printed on separate sheets; it may perhaps be regretted that the scale selected is somewhat minute. It need scarcely be said that the geological relationships of the coal seams and of the various economic minerals met with in the field are described in full detail, and that the memoir, together with the revised maps which it is intended to accompany, will be of the greatest value to mining engineers whose professional work lies in that area of the Scottish coalfield.

A REPORT on the weather experienced at Falmouth Observatory has recently been issued by the Observatory Committee of the Royal Cornwall Polytechnic Society. The observatory is closely associated with the Meteorological Office, and many of the records for Falmouth appear in the several reports of the Office, which probably is sufficient reason for the small amount of work done actually at the observatory. Funds available at the spot are clearly limited, and the staff is, consequently, small. Pressure, temperature, and rainfall results in the report are compared with the means of the forty-five years 1871 to 1915, whilst in the Meteorological Office publications the records are compared with the new normals for thirty-five years, 1881 to 1915. Probably in course of time general uniformity in this respect will be adopted. The mean air temperature for November was a record for cold, and its minimum, 26° F., was the coldest for the year. The total rainfall for the first six months of the year was 5·89 in. greater than for the last six months, which is a reversal of the ordinary rule. October was a record for dryness, rainfall measuring 1·62 in. Bright sunshine had an average record for the year of 4·8 hours per day. October had 158·9 hours, which is a record for that month; the extreme range of the totals for October is 77·6 hours, not 69·2 hours, as stated in the report, for which result 1919 was overlooked. The table of sea temperatures from observations made in the harbour and the comparison with air temperatures is of considerable interest, but the differences from the air of the maxi-

mum and minimum sea values scarcely seem satisfactory, since the observations are not strictly for the same periods, the sea temperatures being for fewer days.

THE Seventh Report of the Industrial Fatigue Research Board (Textile Series, No. 1), dealing with "Individual Differences in Output in the Cotton Industry," has just been issued. It is the result of researches made by Mr. S. Wyatt, Investigator to the Board. The scope of the report represents an attempt to collect information on the question of the relative importance of the human and mechanical factors in various branches of the cotton industry. It is intended to be suggestive rather than conclusive in its nature, to lead on to a careful collection of facts and thence to more detailed and intensive investigations. There is great variety in the conditions obtaining in various types of cotton mills, some, for example, in which, as in the spinning of cotton, the output is almost entirely controlled by the machine, whereby individual differences in ability are reduced to a minimum; while in others, such as in the process of drawing-in by hand, there appears to be much more scope for the expression of individual differences of ability, and therefore of output, by the persons concerned. Thus it may be found possible, where there exist large individual differences of output—which implies that the mechanical factor is subsidiary—so to modify the human conditions of employment that increased efficiency, prosperity, and comfort may result. The inquiry has of necessity been of considerable difficulty, having regard to the variability of the conditions prevailing in the course of preparation and manufacture, yet valuable, if inconclusive, results have been reached, which at least show that the various processes in the cotton industry can be classified and graded according to the magnitude of the individual differences which they produce, wherein lies the relative importance of the human and mechanical forces. Scarcely any attempt has been made in the mills to determine efficiency in the various processes, yet the collection of statistical data would cause the employer and the manager to take a scientific interest in their work, stimulate inquiry and investigation, and lead to improved methods. We may reasonably ask why the workers should not be invited to participate in the research, since it is in their interests also that the best results should be secured.

THE International Institute of Agriculture at Rome has issued the following information with regard to the estimated yields of cereals throughout the world. In the United States the area under winter wheat is considerably smaller than that of last year. Moreover, the season has been somewhat unfavourable, so that the coming crop is estimated at 13·2 million tons, which is 66 per cent. of last year's yield and 86 per cent. of the five previous years' average. It is, however, probable that there are considerable stocks of old wheat still to be exported, and these, together with the reduced new crop, should make the exports for the coming season equal to those for the year ending June, 1920. Drought has considerably affected the crops in Algeria and in southern Italy, and the outlook in Poland is unpromising, especially for rye. In the other countries of the northern hemisphere the condition of the winter cereal crops is normal, while the recent wheat crop in British India shows an increase of 30 per cent. over last year's yield. The maize crop in Argentina is estimated at 30,000,000 quarters, which is 32 per cent. higher than the five previous years' average. This increased yield will probably be an important factor among the cereal resources of the coming season.

THE Journal of the British Science Guild for June contains a special tribute to Lord Sydenham, the retiring president, contributed by Sir O'Moore Creagh. A series of six articles reviews the administrative activities of the Guild, of special interest being the account of the reception by Mr. A. J. Balfour of the deputation on State awards for scientific and medical discovery. The deputation had a sympathetic reception, the justice of the principle being generally conceded, but Mr. Balfour suggested as a difficulty the exact allocation of credit to the authors of scientific discoveries. This problem, it is pointed out by Sir Ronald Ross, has already been dealt with satisfactorily by the Royal Society, the Nobel Prize Committee, and other authorities. It is suggested that pensions and awards might be included in the Civil List. Lt.-Col. W. A. J. O'Meara writes with experience of the need for the utilisation of science in Government Departments. An element of consequence is the concentration of power in the hands of the higher division clerks and the permanent staff, which doubtless militates against the introduction of new ideas. Memoranda by the Health Committee on the milk question raise a number of important points in connection with the purity of supply and the possibility of the communication of diseases through milk. Sir Thomas H. J. C. Goodwin's Chadwick lectures on "Army Hygiene in the War and After" (see NATURE for June 24, p. 532) and Mr. J. J. Robinson's popular lecture on "Knowledge in National Reconstruction," delivered before 1100 members of the Portsmouth Brotherhood, are summarised. The issue is completed by a list of the officers, fellows, and members of the Guild.

THE Ministry of Transport has stated that it is seriously considering the organised electrification of the railways, and the importance of this subject at the present time can scarcely be over-estimated. Sir Philip Dawson's paper on "Electric Railway Contact Systems," which was read to the Institution of Electrical Engineers on June 30, is, therefore, of immediate interest. Before a standard system of electrification can be evolved the question of the relative merits of collecting the current from an overhead system or from a third rail must be discussed. From the data given in the paper a strong case can be made out for overhead collection. The flexible method of suspending the overhead collecting wire on the Brighton Railway has proved thoroughly satisfactory, and the "double insulation" used throughout has reduced breakdowns to a minimum. With third-rail systems it is necessary to pay higher wages to the workmen employed on the line owing to the increased danger. The data given bring out the interesting fact that

the wear of the trolley wire is proportional to the current collected. When no current is taken the wear is almost negligibly small. A curious anomaly in the treatment of railways with and without Parliamentary powers was pointed out. The former railways are not allowed to have more than a 7-volt drop on their rails, whilst the latter have sometimes more than a 100-volt drop for short periods. It seems to us that a careful search should be made in neighbouring pipes, etc., for electrolytic damage in the latter case. If the damage should prove to be inappreciable, then the limit of 7 volts might be raised for all railways, as this would appreciably lower the cost of electrification.

Messrs. Newton and Wright, Ltd., desire it to be known that their business will be carried on in future from their works address, 471–77 Hornsey Road, N.19, which is now the head office of the company. In furtherance of their policy of restricting themselves to a wholesale business, an arrangement has been concluded with Messrs. Allen and Hanburys, Ltd., by which this firm becomes selling agents in the London area for Messrs. Newton and Wright, and also in those parts of the United Kingdom where the latter is not specially represented. Messrs. Allen and Hanburys are taking over the electro-medical showroom at 72 Wigmore Street, W.1, until recently occupied by Messrs. Newton and Wright, who will, however, have free access to these showrooms, and one of their directors will always be glad to meet country and other customers by appointment who may not have time to visit the head office at Hornsey Road. The arrangements with Messrs. Allen and Hanburys are so framed as not to preclude Messrs. Newton and Wright doing business with other trade houses, and the firm will be pleased to continue supplying their specialities through whatever trade house a customer may select.

The special catalogues of Messrs. J. Wheldon and Co., 38 Great Queen Street, W.C.2, are always of interest and value, and the latest (New Series, No. 90) is no exception. It is a well-edited, classified list of upwards of 1200 books and pamphlets on ornithology. The sections are British Islands, Europe, Asia, Africa, North America, Central and South America, Australasia, General Systems, etc., Economic Ornithology, Miscellanea, and Morphology. Many scarce works are included. In addition, particulars are given of many complete sets or long runs of scientific journals. The catalogue should be of service to purchasers of books of science.

Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1, have just circulated the quarterly catalogue of new books and new editions added to their Medical and Scientific Circulating Library during the months April–June. It is a useful classified list of the works in science published in the period named, and should be found useful even to non-subscribers to the library. Messrs. Lewis have also issued a list of second-hand and surplus library books an agriculture, botany, chemistry, engineering, geology, physics, zoology, etc. Many of the volumes are offered for sale at greatly reduced prices.

Our Astronomical Column.

A New Comet.—The second cometary discovery of the year was made at Nice by M. Schaumasse on July 18 at 13h. 37·1m. G.M.T., in R.A. 1h. 47m. 52s., south decl. 1° 14′, daily motion +2m. 24s., S. 5′, 11th magnitude.

The following positions have been deduced on the assumption of uniform motion:

	R.A. h. m. s.	S. Dec ° ′
July 23 ...	1 59 43	1 39
28 ...	2 11 43	2 4

The comet is a morning star, rising at 1 a.m. summer time. It is not very far from Tempel's comet, discovered at Kyoto at the end of May, but of which no further observations have come to hand.

Later.—M. Schaumasse now finds that his new comet is identical with Tempel's second periodic comet, the previous announcement by Mr. Kudara, of Kyoto, being erroneous. The time of perihelion now becomes 1920 June 9·67, a month earlier than the time deduced from Mr. Kudara's announcement.

The following is an approximate ephemeris for Greenwich midnight:

	R.A. h. m. s.	S. Decl. ° ′	Log r	Log Δ
July 15	1 40 4	1 14	0·1402	9·9674
23	1 59 24	1 26	0·1488	9·9623
31	2 16 40	1 53	0·1585	9·9577
Aug. 8	2 30 52	2 36	0·1693	9·9522
16	2 42 32	3 33	0·1805	9·9467
24	2 50 48	4 47	0·1920	9·9403

Publications of the Dominion Astrophysical Observatory, Victoria, B.C., Vol. i., No. 1.—This volume contains a full account of the inception of the scheme of constructing the great 72-in. equatorial, and demonstrates the immense amount of careful thought and consultation of experts, both opticians and astronomers, that preceded the adoption of the designs.

Before the site was settled, Mr. W. E. Harper tested the quality of seeing at a number of stations in different parts of Canada, using a 4½-in. Cooke photo-visual telescope. Victoria was finally selected, owing to the excellent seeing at night, though there was less sunshine than at Ottawa; the small diurnal range of temperature also favoured it.

The glass discs were cast at St. Gobain, the optical work was entrusted to the J. A. Brashear Co., and the mechanical work and dome to the Warner and Swasey Co.

The ball-bearings, in dustproof cases, prove very efficient, so that it is stated that when the clock is disconnected a 3½-lb. weight on a 26-ft. arm suffices to set the telescope in motion; a 400-lb. weight is found sufficient for the driving clock, which is wound automatically by an electric motor. The volume contains details of the zonal tests applied to the mirror, the results being very satisfactory. Temperature insulation, consisting of cotton-felt, is used round the mirror, and with the small temperature changes that take place at Victoria the definition will never be appreciably affected by this cause.

The comfort and convenience of the observers are studied, all the movements being carried out electrically. Details are also given of the powerful spectrograph, which is surrounded by a temperature-case. It is possible to use the instrument visually without removing the spectrograph, the image being displaced laterally by reflecting prisms.

Numerous large-scale photographs of the various parts make it easy to follow the descriptions.

Progress in Science and Pharmacy.[1]

By CHARLES ALEXANDER HILL.

TWENTY-FOUR years have passed since the British Pharmaceutical Conference met in this great city of Liverpool. On that occasion the late William Martindale in his presidential address dealt with the use in medicine of "active principles" in substitution of the natural, *i.e.* naturally occurring, drugs. At the same time he described the introduction of synthetic substances into medicine as a novelty.

To-day it is fitting to reflect upon the changes in pharmacy wrought by progress in science—progress in chemistry and biochemistry, in physics, in physiology, and in the science and practice of medicine; next, to examine the extent to which active principles and synthetics have replaced natural drugs; then tentatively to survey the lines upon which future development may be expected.

Of the changes that have occurred the increased use of synthetic drugs is the outstanding, though by no means the only, feature. It is noteworthy that important discoveries of new vegetable drugs are practically unknown. The animal kingdom, on the other hand, has furnished us with drugs of the first importance; of these the products of the pituitary body, the thyroid gland, and the suprarenal gland afford notable examples. The importance of these discoveries is in nowise diminished if the active principles have been synthesised and can be produced artificially.

The use of synthetic remedies in medicine is sometimes said to date from the introduction of antipyrin in 1884, but chloroform and chloral hydrate had long been known and used, and synthetic salicylic acid was freely used in 1877. Hypnone (acetophenone) followed in 1885 and antifebrin (acetanilide) in 1886. These were succeeded by phenacetin, sulphonal, and trional, and since then there has been a steady flow of new synthetic drugs.

To-day the world's annual consumption of phenazone or antipyrin may be roughly estimated at 100 tons, of phenacetin at 250 tons, and of medicinal salicylates (sodium salicylate, methyl salicylate, aspirin, and salol) at no less than 2500 tons, and these are a few only out of the multitude of pure chemical substances used in medicine.

Notwithstanding the remarkable extent to which synthetic drugs have come into use, and despite the increased employment of active principles according as our knowledge of these progresses, the use of the drugs themselves in the form of galenical preparations, whether "standardised" or not, continues to a remarkable, and perhaps significant, extent. Furthermore, as we shall see, signs are not wanting of a growing recognition of the truth that many a drug and many a food may contain valuable properties not readily determined by chemical methods. It may be only slowly that the full value of a drug discovered empirically can be stated in scientific terms. Paradoxical as it may seem, the tendency to-day, with advancing scientific knowledge, is to recognise the failure of the active principle to replace the parent drug.

When it happens, the replacement of a natural drug by a synthetic substance may be conceived as proceeding ideally in four stages. First, the drug is examined chemically, and from it is isolated a pure substance, frequently an alkaloid or a glucoside, which upon being subjected to physiological tests is found to have an effect similar to that of the parent drug; such a substance is termed the "active principle" of the drug. The second stage is to determine the chemical constitution of the isolated active principle; this, in general, is a matter of extreme difficulty, taxing the resources of our most brilliant organic chemists, which, indeed, is equally true of the third stage, which consists in effecting the synthesis of the substance. Once the synthesis has been successfully accomplished we arrive at the fourth and last stage, which is the manufacture of the substance upon a commercial scale. The case of suprarenal gland and adrenalin affords an illustration.

It does not follow as a matter of course that if the synthesis of a substance be accomplished the artificial or synthetic article will replace the naturally occurring one. Supposing quinine were to be synthesised, it is by no means to be assumed that it would be cheaper to produce it on a large scale in the laboratory than to get Nature to conduct the synthesis, and then to extract the alkaloid from cinchona bark and afterwards purify it. It has been amply illustrated in the case of cinchona bark that it pays to subsidise Nature and to encourage her to increase her yield. Intensive culture may be a better business proposition than laboratory manufacture.

Synthetic Drugs.

By far the larger number of chemical substances used in medicine are not the active principles of natural drugs. It would lead me beyond the confines of my address to attempt even a cursory survey of what has been accomplished in the limitless field of synthetic drugs, to the enormous consumption of which I have already made reference, or to make more than the barest mention of the fact that synthetic organic substances are employed as antiseptics, anæsthetics, narcotics, hypnotics, and antipyretics, and in the treatment of diseases, notably those of parasitic origin.

Nor need I remind you of the many attempts made by chemico-physiologists to correlate chemical constitution and physiological action. Much chemical and physiological work has been done in this fascinating field of research, and certain generalisations have resulted by deductive reasoning from very numerous data, yet it has to be admitted that really very little is known of this borderland subject. The physical condition of the substance, its solubility, especially its relative solubilities in different solvents ("partition coefficient"), its adsorptive power, osmotic properties, and other physical properties, have as much to do with its physiological action as has its constitutional formula.

It may indeed be that the purely chemical action of a drug is destined to play a subordinate *rôle* in therapy, and that, in the past, the physical action has not been sufficiently considered.

Chemotherapy shows us clearly that the physiological action of a substance is not due to one constituent only of that compound, but that it also depends largely upon the molecular orientation of the compound and the ratio of adsorption which exists between it and the protein colloidal particles through which this or that constituent is going to act. Consider arsenic, for example. In the treatment of disease plain liquor arsenicalis is not so effective as colloidal arsenic sulphide, nor is the latter so effective as arsenophenylglycine, nor the last so effective as diaminoarsenobenzene. They all contain arsenic, but the last, in virtue of its amino-groups, is able to be adsorbed in very large quantities by the protein colloidal particles; consequently, the greatest amount possible of the element gets taken up. So far as can be seen at present, the amino-groups are of great

[1] From the presidential address delivered at the Royal Institution, Liverpool, on July 20, at the fifty-seventh annual meeting of the British Pharmaceutical Conference.

importance in a chemotherapeutic compound, especially if they can be placed in the ortho-position to the element one wishes to incorporate.

Of greater importance than the group is the molecular orientation; one needs only to mention the effect of introducing an acetyl group to illustrate this point. Compare diorthoaminothiobenzene with its acetyl derivative; the former is practically a specific for metallic poisoning, while the latter is as inert as plain colloidal or sublimed sulphur. Even diparaaminothiobenzene cannot compare with the orthobody. The addition of an acetyl group to salicylic acid results in a new analgesic property, while at the same time the undesirable after-effects of salicylates are in some measure eliminated. A similar addition to phenetidin gives us phenacetin with its valuable antipyretic properties. On the other hand, the addition of an acetyl group to parahydroxyphenylethylamine (an active principle of ergot) results in a loss of activity. The introduction of an acetyl group into the choline molecule converts this comparatively inert substance into a powerful heart poison. Highly interesting is the case of aconitine. This intensely poisonous alkaloid is the acetyl derivative of benzaconine, the latter substance being relatively non-toxic. Yet the introduction of further acetyl groups into the aconitine molecule does not increase, but diminishes, its toxicity.

Recent Advances in Biochemistry.

Theoretically, every ingredient of a drug or preparation must have some effect, though it may be so small as to be inappreciable by any known means; and some drugs and foods have constituents minute in quantity, and therefore long unknown, of the very highest degree of importance. Indeed, recent advances in biochemistry have proved the existence in drugs and foods of physiologically active substances which give a rational explanation of facts based upon experience and established empirically.

Fresh in the memories of all of us is the discovery of the cause and cure of beri-beri, constituting one of the romances of medical science. Beri-beri is a disease of a high mortality which ravaged tropical countries and caused much misery. It had long been connected in the minds of the investigators with the rice which formed the staple food of the populations affected by it, but it has only recently been discovered that the disease is caused by the refinements of rice-milling, brought about by the introduction of machinery. It was observed by Eijkmann, the medical officer to a prison in Java, that the poultry of their establishment suffered from symptoms remarkably like those of beri-beri, which was common in his gaol, where the inmates were fed on a rice diet. Investigations showed this observer that the fowls could be quickly cured by adding to their diet the pericarp and embryo of rice removed during the process of milling.

From this starting point there was established by research a complete correlation between the occurrence of beri-beri and the consumption of steam-milled rice. In districts where rice is polished by hand the disease does not frequently occur, because it rarely happens that the whole of the pericarp and embryo are removed by hand. Fowls fed on polished rice quickly suffered from polyneuritis, and birds almost at the point of death were quickly rescued, it was found, by the administration of a watery extract of rice polishings. Thus was beri-beri found to be caused by the absence from the diet of a substance soluble in water and present in rice polishings.

This water-soluble constituent belongs to a class of accessory food substances which have been somewhat unfortunately named "vitamines." Work on these vitamines can scarcely be said to have a chemical basis, since all attempts to isolate them have failed. At least three have been recognised: (1) water-soluble B factor, which prevents beri-beri, occurs in the seeds of plants and the eggs of animals, in yeast and liver and grain cereals.

Scorbutus or scurvy is a disease which in former times caused high mortality. Sailors particularly were subject to attack, this being due to the fact that they were not obtaining another water-soluble vitamine, (2) the anti-scorbutic factor. The disease yields readily to a diet of potatoes, cabbages, and most fresh fruits.

Thirdly, there is a fat-soluble vitamine; this is present in cream and butter and beef-fat, and affords us a rational explanation of our natural preference for real butter over vegetable margarine. Cod-liver oil, which may be regarded as intermediate between foods and drugs, has long enjoyed a deservedly great reputation as possessing qualities superior to those of other oils. These qualities are due to the fact that good cod-liver oil has a high vitamine content, and is therefore important in the prevention and cure of rickets. On the other hand, vegetable oils, such as linseed, olive, cottonseed, coconut, and palm, contain only negligible amounts of this vitamine.

Biochemistry shows us the importance of other accessory substances besides vitamines. Enzyme action has been shown to be modified or stimulated by the presence of other substances termed co-enzymes. Parallel phenomena have been observed in the digestive processes of mammals in the remarkable activating nature of bodies termed hormones.

It would be beyond the limits of my address to go further than these somewhat brief indications that naturally occurring drugs and foods contain substances that long remained unsuspected and still longer unrevealed, but quite enough will have been said to show how unsafe it is to substitute one thing for another.

Research.

It is not easy to state concisely what is to be distinguished as pharmaceutical research. All will agree that it means something more than an improvement in processes for the exhibition of drugs in pharmaceutical preparations. Does it mean problems arising out of the cultivation of drugs not hitherto grown within the Empire, or the intensive cultivation of indigenous drugs with a view to increased activity, or the chemical investigation of drugs for their active constituents; or, again, does it mean research in organic chemistry for the production of new synthetic remedies, or does it mean pharmacological experiments, or all of these things? I would submit to you the following consideration: We have seen that pharmaceutical preparations of drugs continue to find employment even after the active principles of those drugs have been isolated, and are readily available in a pure state. We have seen that drugs and food-drugs are found to have valuable properties which cannot be stated in definite terms in the present state of our knowledge. Further than this, as our knowledge of such bodies as vitamines, enzymes, and hormones advances, so increases our respect for the natural source of such bodies—they may be glands or they may be seeds—whether as a food or as a remedial agent. Such may be the fate of many an "old-fashioned" remedy about which hard words have been used merely because it was not fully understood. Here then, it seems to me, is presented a most fitting subject for pharmaceutical research: to determine and control the conditions of collection and preparation of the parent drug, the process of treatment and manufacture and the conditions of storage, to dis-

cover characters and devise tests within the scope of the skilled, trained pharmaceutical chemist without involving experiments upon living animals, so that the pharmaceutical preparation exhibiting the drug shall be both active and uniform.

The Future.

The annual meeting of the British Pharmaceutical Conference affords a great opportunity for all pharmacists to meet each other on common ground and consider their common interests. Is not the present a period in pharmaceutical history at which it is fitting that all of us whose lot is cast in pharmacy should band together for our common welfare? The demands of the business side of pharmacy are to-day so imperious and so obvious that there is a danger of neglecting what, to my mind, is of primary importance if we are to persist. If I am asked what path should be pointed out for pharmacists to pursue in order that the present condition of affairs may be improved and the outlook for the future made more bright, then I say without doubt that the answer lies in cultivating assiduously the scientific side of pharmacy; in the promotion, encouragement, and assistance of pharmaceutical research; in the improvement of pharmaceutical products; and in keeping pharmacy abreast of advances in chemistry, physiology, bacteriology, vaccine-therapy, and other kindred subjects.

Only by giving first place to the professional side of pharmacy, keeping as distinct as possible the purely business side and declining to mix with pharmacy proper business in things so far removed from drugs as to be derogatory to the calling of pharmacy—only thus will it be possible to maintain and enhance the esteem in which pharmacists are held by their fellow-men, both medical men and laymen, as well as public bodies and Government Departments.

The British Pharmaceutical Conference exists for "the cultivation of pharmaceutical science" and "to maintain uncompromisingly the principle of purity in medicine." Let pharmacists see to it that the conference receive full and generous support, and that no effort be spared to enable it to carry out these worthy objects. Thus shall pharmacists prosper and pharmacy flourish.

Medical Science and Education.

IN his wisely eloquent presidential address to the British Medical Association meeting at Cambridge Sir T. Clifford Allbutt struck many a nail on the head. He began with the claim that the universities, ancient and modern, from Alexandria to Edinburgh, have made the professions, and stated the university ambitions to be building up character, training in clear thinking, and imparting particular knowledge and experience. He confessed, however, that the new universities compare ill with the old in nourishing the imagination. There is need to learn how to teach; there is need for simplification by more blending of details into larger principles; and there is need to beware of letting our teaching stiffen into formulas. Another point, refreshingly illustrated, was the debt of other sciences to medicine, for what impulses have come from medical studies to cytology, to organic chemistry, to bacteriology, and so on, up to philosophy, as the address itself shows. In medical research, as elsewhere, natural observation is yielding more and more to artificial experiment as investigation penetrates from the more superficial to the deeper processes. "The progress of medicine must in large part be endogenous." "Mere observation—Nature's march past—will not count for much now; and as to family histories—well, they vary with each historian." Once more Sir Clifford Allbutt made a plea for the study of the elements and phases of disease in animals and plants—a comparative pathology that would stir the imagination of young workers and save the world from a wastage as unnecessary as it is incalculable. "Yet no one stirs, save to gyrate each in his own little circle. There is no imagination, no organisation of research, no cross-light from school to school, no mutual enlightenment among investigators, no big outlook. . . . How blind we are!" After a very severe but timely criticism of psychotherapy—a criticism which is not marked, however, by any lack of appreciation of the fruitfulness of experimental psychology—Sir Clifford Allbutt closed with some discussion of the immediate problems of general practice and preventive medicine. There is inspiration in the whole address (see *British Medical Journal*, No. 3105, pp. 1–8), not least in its final glimpse of the possibilities before medicine as a social service and international bond.

At the same meeting of the British Medical Association there was an exceedingly important discussion on the place of "preliminary science" in the medical curriculum—a discussion which will lead, we hope, to some highly desirable changes. In his introductory address Sir George Newman indicated several reforms—a quantitative lightening of the curriculum at both ends, a fresh orientation of the preliminary sciences in relation to the training of medical students, but, above all, more biology and more real biology. "It is the biological outlook and spirit that is required, the capacity 'to see great truths that touch and handle little ones'; for biology, pure and applied, is the most educative, germinative, and dynamic subject in the whole curriculum." Prof. S. J. Hickson emphasised the value of biological studies in cultivating habits of verification and precision, in preparing the ground for subsequent anatomical and physiological studies, and in introducing the student to practically important sets of facts, either very concrete as in the case of parasites and their carriers, or more theoretical as in the case of heredity. He recommended a reduction in the number of "types" so as to make room for more important studies, better orientation of what is taught, and more emphasis on fundamental questions—admittedly difficult as it is to handle them well in teaching beginners. Prof. A. Keith urged that "anatomy could be made a living, practical part of medicine if only the teacher would ask himself: Could this fact help me in diagnosis and treatment?" Sir Ernest Rutherford, speaking of physics, insisted on the necessity for a sound training in the fundamental methods and principles of the science before the medical curriculum is begun, and for a subsequent professional course oriented in a judicious way to future studies in physiology and the like. Prof. Lorrain Smith laid emphasis on the fundamental value of the preliminary sciences as a training in method and criticism, but maintained that the general introduction at present supplied is wasteful in its discontinuity with what follows later. It misses part of its aim because its bearings on more professional studies are not made clear. Prof. A. Smithells, speaking of chemistry, indicated some ways in which more value could be got out of the present opportunities if there were more adjustment to the particular ends in view. In general, there seemed to be agreement (see *British Medical Journal*, No. 3105, pp. 8–21) on two points: (1) The need for making sure of a firmer grasp of principles, and (2) the need for a re-orientation of the class-teaching in relation to the particular needs of the medical student.

First Conference of the International Federation of University Women.

THE International Federation of University Women held its first conference at Bedford College, London, on July 12–14, and it has been interesting to note how thoroughly the Federation deserves its name. If Great Britain and the United States were the most numerously represented, as they are the founder nations, there were plenty of other nationalities to meet them. France, Spain, Italy, Holland, Belgium, the Scandinavian countries, Czecho-Slovakia, India, and the Overseas Dominions of the British Empire had all sent their delegates to participate in the conference. The proceedings opened on the evening of July 12, when a large audience listened to speeches by Lord Grey of Fallodon, Prof. Caroline Spurgeon (Bedford College), Dean Virginia Gildersleeve (Barnard College, New York), and Prof. Winifred Cullis (the London School of Medicine for Women). Lord Grey emphasised the necessity for intercourse between the peoples of the world, and the women speakers outlined the means by which the International Federation intends to promote this necessary contact between the women of the universities of the world. Briefly, their aims are the establishment of travelling fellowships and international scholarships; the exchange of professors, lecturers, and students; the establishment of club-houses and other centres of international hospitality; and useful co-operation with the national bureaux of education in the various countries.

On the following days the foundations of the Federation were established. A constitution and by-laws were freely discussed and considerably amended before final adoption. The effect of these will be to establish a central office in London for general information, which will operate in connection with Committees on International Relations set up in each country which is a member of the Federation. Officers have been elected for the ensuing two years, the president being Prof. Spurgeon; the vice-president, Mrs. R. F. McWilliams, of Winnipeg; the treasurer, Mrs. Edgerton Parsons, of New York; and the secretary, Miss T. Bosanquet, assistant secretary to the Universities Bureau of the British Empire, 50 Russell Square, W.C.1.

Informal reports on the position of the higher education of women in the various countries represented were read, and steps will be taken to correlate the academic standards in the different universities.

The next meeting will be held in the summer of 1922. It is hoped that in the meantime each branch association of the Federation will work actively to further the aims of the Federation in its own country. The British Federation of University Women is losing no time in getting to work, and will initiate a campaign for the programme of the International Federation in the autumn.

Insect Pests.

IN connection with tropical agriculture, attention has been directed to the question of the influence of the condition of the host-plant on infestation with sucking insects. It is believed that such pests as thrips on cacao and froghopper blight on sugar-cane can be held in check by increasing the resistance of the plant by improving agricultural conditions. In the *Agricultural News* (vol. xix., No. 464) it is claimed that the "mosquito blight" of tea (caused by a capsid bug of the genus Helopeltis) is affected in a similar way, and that the condition of individual tea-bushes determines the susceptibility to attack. The distribution of mosquito blight appears to be connected with soil conditions, and analytical data indicate that soils on which the pest is prevalent show similarities in the potash-phosphoric acid ratio, the addition of potash having an appreciable, though irregular, action in reducing the blight. Water-logging tends to encourage infestation, probably because the vitality of bushes grown on such areas is lowered; draining is the remedy advised in such cases. Acidity and poverty of soil are other factors which vitiate the health of the tea-bushes, so rendering them more liable to attack.

The spread of prickly pear in Australia is so rapid that large areas of land will continue to be thrown out of cultivation year by year unless some effective measure of control can be devised. It is estimated that the pest claims for its own 1,000,000 acres of fresh land per annum. Various methods of eradication have been tried, but destruction by mechanical or chemical means has proved too expensive for use on a large scale. The pear cannot be fed off to stock, and the manufacture of potash and paper from it has not proved to be commercially successful. A fourth line of attack—destruction by natural enemies—is now being followed up (*Science and Industry*, vol. ii., No. 1). It is necessary to find some enemies of the prickly pear that will not attack other vegetation, as the introduction of "omnivorous vegetarians" would probably result in serious injury to other forms of plant-life. For this reason certain rodents, snails, and insects which are known to feed on prickly pear in America and Africa cannot be recommended for introduction into Australia. One insect, however, *Coccus indicus*, appears to feed exclusively on one form of pear, *Opuntia monocantha*, but unfortunately it will not feed upon the chief pest, *O. inermis*. It is recommended that experiments should be carried on to induce the insects to transfer their attention from one species to the other, if necessary by means of hybridising the pears. Other insects—bugs, flies, moths, and beetles—are known to feed upon one or other species of prickly pear, and it is possible that useful enemies might be introduced from Mexico and South America.

The loss caused by the jointworm flies of the genus Harmolita (Isosoma) in the United States runs into millions of dollars per annum, the wheat jointworm (*H. tritici*) being the greatest devastator. W. J. Phillips (Bull. 808, Professional Paper, U.S.A. Dept. Agric.) has gathered together the available information and classified the species into groups that attack grain crops, cultivated grasses, and wild grasses. The two first groups cause considerable loss by the injury they entail to the crops. The members of the last group, however, may possibly be beneficial in an economic sense, as they provide intermediate hosts for the parasitic insects which prey upon the genus, the more important parasites being common to the majority of species of Harmolita. The life-histories of several species are described, together with the way in which injury is caused to the plants attacked. *H. tritici* causes the most serious losses, reducing the yield of wheat by as much as 50 per cent., the grains being somewhat small and shrivelled. *H. grandis* is also confined to wheat, and produces two generations in the year, but as it is easily controlled its powers of destruction can be kept in check. Breeding experiments indicate that each species is probably confined to a single host, as it has proved impossible to induce the more important forms to attack other crops than that with which they are normally associated. The jointworms are much subject to parasitic attacks, and for this reason do not often get quite

out of hand and destroy an entire crop; but, even so, they exact a toll of from 1 to 5 bushels per acre unless control measures are adopted. Experiments seem to show that ploughing under the stubble is the most effective remedy, as wholesale destruction of the insects is thus brought about. It would be necessary to arrange the crop rotation so as to allow the wheat-stubble to be ploughed up, but if this could be done it is estimated that millions of dollars could be saved yearly.

Parasites such as lice and mites cause considerable loss in the poultry industry by reducing egg-production and injuring the quantity and quality of the flesh of the birds. A cheap but effective remedy is therefore much to be desired, and it is now claimed by F. C. Bishop and H. P. Wood (Farmers' Bulletin 801, U.S.A. Dept. Agric.) that sodium fluoride fulfils these conditions, and that, if properly used, one application will completely destroy all the lice present on any bird. The treatment can be carried out by dusting or by dipping. In the former case pinches of the fluoride are placed among the feathers close to the skin on the parts most frequently attacked; dusting with a shaker is less effective, and also causes more irritation to the nose and throat of the operator. In the latter case ¾–1 oz. of commercial sodium fluoride is dissolved in a gallon of tepid water, and the birds are then dipped for a few seconds. The lice die more rapidly in this case than when the dry powder is used. It is estimated that the cost of treatment works out to about one farthing per bird, 1 lb. of sodium fluoride sufficing for about a hundred hens.

Investigations of the Upper Air.[1]

THE interesting publications referred to below deal with the investigation of the upper air, the first two being written in German. Dr. Everdingen, in Holland, has experienced the same difficulty that has occurred in England and elsewhere in carrying on the investigation owing to the scarcity and badness of the necessary materials, on account of which the mean height of the kite and captive-balloon ascents, when compared with that of previous years, was reduced considerably. The two years' reports contain full particulars of each ascent made; they are noteworthy as showing the increasing importance of aeroplanes compared with the old method of kites as a means of observation.

The third publication, Geophysical Memoirs, No. 14, gives an account of the pilot-balloon ascents made in November and December, 1911, by Capt. Cave and Mr. J. S. Dines in the Scilly Isles. Plenty of information about the relation of the wind to the surface-pressure gradient up to a few kilometres height over land is available, but similar information about the wind over the sea is very scarce. The expedition to the Scilly Isles was planned and carried out by Capt. Cave expressly to meet this want, and the results, which contain a large and useful amount of information, have at last been published.

The islands are noted for their fine formation of rock, and they are exposed to the full force of the Atlantic gales; in no part does the surface rise much above the sea-level, and the whole land area is small, thus the influence of the land on the air-currents must also be small. Moreover, except to the south-west, readings of the barometer are available, and hence the isobars on the daily weather charts can be drawn in the neighbourhood of the islands with fair precision.

The balloons were mostly followed by two theodolites at the ends of a base line of 5260 metres, but on a few occasions, on account of the difficulty of reaching the distant station, only one was used. The period covered was from November 22 to December 8. The weather was mostly rough and stormy with a prevalence of clouds, so that the balloons could seldom be followed to any great height, but the conditions were very favourable for the purpose of the observations. The authors found, as they expected, that the effect of surface-friction is far less at St. Mary's than inland, and they give the loss of velocity at the anemometer head at Scilly as 20 per cent., against 35 to 50 per cent. at Ditcham Park.

The question of the rate of ascent of pilot balloons is considered. The same kind of balloon was used as at Ditcham Park and the same free lift given. The mean rate of ascent was 160·6 metres per minute. It has been found inland that balloons show a tendency to rise faster in the first half kilometre, but this was not the case at Scilly. The rate of ascent varied considerably from minute to minute, but no systematic difference was found, and hence the authors conclude that the general results obtained from single theodolites may be looked upon as quite trustworthy

The last section deals with the type and height of the clouds prevalent during each ascent, and some evidence was found of the motion of the upper clouds away from the centre of the depression which dominated the weather at the time.

The whole memoir is very interesting and should be read by every student of meteorology.

Bionomics of *Glossina palpalis.*

NO. XVII. of the Reports of the Sleeping Sickness Commission of the Royal Society (H.M. Stationery Office, price 4s. net), which has recently been issued, includes the third, fourth, and fifth reports on the bionomics of *Glossina palpalis* on Lake Victoria by Dr. G. D. Hale Carpenter, of the Uganda Medical Service.

Interesting descriptions are given of the natural features and of the fauna and flora of the thirty-six islands visited. These should be consulted in the original by those interested. From a study of the conditions prevailing in these islands it was deduced that the conditions for the prevalence of fly above the average are (1) suitable breeding-grounds, viz. dry sand or gravel ridges representing old lake-shore levels; (2) abundant shade combined with open spaces to permit of the movements of the fly; and (3) absence of large spiders (? Nephila).

The characters of a suitable breeding-ground are the following: (1) Loose soil, (2) dry soil, (3) well-ventilated soil, (4) adequate shade, and (5) within 20–30 yards of water. Further research will probably enable us to define these conditions still more precisely and to decide whether they, as one would expect, are also the optimum for the development of pupæ.

The practical suggestion is made that fly may be controlled by constructing artificial shelters with the characters above defined which would be attractive to the fly as breeding-grounds, and where the pupæ would be regularly collected and destroyed. It might be possible to add some chemical to the soil in these shelters which would obviate the necessity of collection and destruction. The author has established the fact that flies pupate in these shelters.

[1] "Koninklijk Nederlandsch Meteorologisch Institut," No. 106. "Ergebnisse Aerologischer Beobachtungen," parts v. (1916) and vi. (1917). Air Ministry. Meteorological Office. Geophysical Memoirs, No. 14: "Soundings with Pilot-balloons in the Isles of Scilly."

The report is an example of [illegible] methodical collection of data. Whether [illegible] destruction or control of Glossina, which seemed at first sight an almost hopeless quest, can be achieved by this method we shall no doubt soon learn.

J. W. W. S.

Dante and Trepidation.

IN a note entitled "La trepidazione in Dante?" (Atti della R. Accad. di Torino, vol. lii., p. 353) Signor O. Z. Bianco discusses the novel interpretation given by Duhem ("Le Système du monde," t. iv., chap. x.) of a well-known passage in the "Paradiso" (xxvii., 142–48):

> But ere that January pass to spring
> Through that small hundredth men neglect below,
> These higher spheres shall with loud bellowings ring;
> The tempest fierce, that seemed to move so slow,
> Shall whirl the poops where now the prows we see,
> So that the fleet shall on its right course go;
> And following on the flower, the true fruit be.
> (*Plumptre's translation.*)

The first two lines clearly allude to the difference between the Julian year and the true value of the tropical year, which Dante assumed equal to 1/100 day, the neglect of which was gradually making the spring equinox occur earlier, and would (if the error were not corrected) eventually make the spring begin in January. Duhem suggested that the second half of the passage alludes to the so-called trepidation of the equinoxes. According to the theory formulated by Tâbit ben Korra in the ninth century, the equinoxes do not move uniformly from east to west, but alternately advance and recede in a period of more than four thousand years. This imaginary phenomenon is not alluded to by Al Fargani, from whose text-book Dante seems to have derived his astronomical knowledge. Signor Bianco rejects Duhem's suggestion, which is at variance with what Dante says elsewhere ("Convito," ii., 6; "Purgat.," xi., 108) about the slow motion of 1° in a hundred years. It is surely much more natural to suppose that the poet simply meant that long before the spring equinox after some thousands of years had moved back into January, great upheavals would take place in Italy.

Japanese Botanical Work.

THE Journal of the College of Science of the Imperial University of Tokyo, vol. xliii., contains (article 1) an admirably illustrated monograph (in English) of the genus of brown seaweeds, Alaria, by Prof. K. Yendo. The author has studied the various species on the west coast of Vancouver Island, along the coast of the Kurile Islands and of Kamtschatka as well as in Japan, and also the material in some of the important European herbaria. The descriptive portion is preceded by a general account of the morphology, structure, and development. The vexed question of the cryptostomata in the brown seaweeds is discussed at some length, and the author concludes that these tufts of hairs, at any rate in the Laminarias, may be regarded as absorptive organs. A *résumé* is also given of the differing views held as to the life-history, especially as to evidence on the manner of renewal of the blades, of Alaria, which, the author considers, "may be either gradual or sudden, according to the conditions of the place where the plant grows." As regards the economic uses of Alaria, though *A. esculenta* was extensively used for food in earlier times in North-West Europe, and this and other species are still eaten in various sub-Arctic areas, the author concludes that the genus has very little value as human food or for kelp-ash. For manure it may be used equally well with other brown seaweeds. The species inhabit the colder northern seas, the greatest number being found within a range from about 42° N. up to the Arctic Circle. Fifteen species are recognised. Of these full descriptions are given, variations in form and synonymy are discussed, and a list of localities is cited. The form and structure of the species are illustrated in nineteen excellent double-page plates.

The same volume contains a short paper (article 2) by T. Matsushima describing investigations on the transpiration of cut branches, and an ecological study (article 3) by Y. Yoshii of the Ota dunes—both in German.

In the "Icones Plantarum Formosanarum," vol. viii., Bunzo Hayata continues his descriptive work on the flora of the Island of Formosa, based on the study of the collections of the Botanical Survey of the Government of Formosa. The present volume contains descriptions of species and varieties of flowering plants in various families, and of ferns; 111 new species and 17 varieties are included. The total number of species of the flora is brought up to 3458, contained in 1174 genera representing 169 families. The genus Citrus (orange, lemon, etc.) is treated at some length, as also are the figs, Ficus, of which the author recognises 29 species in Formosa. In addition to eighty-eight text-figures, the species are illustrated by fifteen excellent full-page plates showing habit and floral dissections.

Researches on Egyptian Cotton.

THE newly appointed Cotton Research Board for Egypt has issued a Preliminary Report, in which a sketch is given of the general significance of the Egyptian cotton crop and the formation and proposed operations of the new Board are described. Plans of the buildings under construction are shown, and a few illuminating figures serve to bring home to the reader the immense volume of detailed information required in the modern study of crops. An outline of the field of work to be undertaken by a staff of eleven non-Egyptian scientific workers and twenty Egyptians is given for the botanical, entomological, chemical, and physical sides, though the Board is rightly careful not to bind itself to a definite programme.

Those interested in cotton or in Egypt cannot fail to be very glad that this Board has at last come into existence, but the matter is of wider interest in that a move has here been made towards the separation of administration from research. Both functions have been hampered in the past history of many agricultural services by mutual confusion, and we anticipate that the step taken by Egypt in this matter will be generally adopted.

The only criticism we would offer on this report is upon the reason given for the establishment of the Board, to wit: "Past experience of . . . the disadvantages attaching to the investigation of cotton problems from the point of view of any one branch of science." We would rather have judged that Egyptian cotton had been singularly fortunate in the informal and voluntary co-operation of every branch of science, the schools of medicine and engineering, and the departments of survey and geology, as well as the agricultural organisations, having given invaluable help in all directions. We would suggest that past experience showed rather the need for a body (such as this Cotton Research Board) which would

cut across departmental boundaries, and give official status and help to the scientific co-operation already in existence. It is to be hoped that the Board may ultimately see its way so to extend its ranks as to effect *liaison* with bodies outside the official Egyptian Service.

W. LAWRENCE BALLS.

University and Educational Intelligence.

CAMBRIDGE.—Applications are invited for the George Henry Lewes studentship in physiology, value 245*l*. Candidates must send their applications, with particulars of their qualifications and the subject of their proposed research, by July 31 to Prof. Langley at the Physiology School.

A further gift of 6000*l*. has been received from Mr. and Mrs. P. A. Molteno to meet the increased cost of labour and material in the building of the Molteno Institute of Parasitology. This avoids the need to reduce the accommodation originally proposed.

Mr. R. H. Vernon, Gonville and Caius College, has been appointed assistant to the professor of chemistry.

Honorary degrees are being conferred on the Spanish Ambassador, the President of Harvard University, Prof. H. Cushing, and Prof. J. J. Abel.

GLASGOW.—The following were among the degrees conferred on July 19:—*Doctor of Medicine (M.D.)*: (i) With Commendation: James Gordon Wilson—thesis, "A History of Influenza and its Variations." (ii) Ordinary Degrees: Albert Barnes Hughes—thesis, "Puerperal Eclampsia"; Donald MacKenzie MacRae—thesis, "The Bechuanaland Protectorate: Its People and Prevalent Diseases, with a special consideration of the effects of tropical residence and food in relation to health and disease"; and John Young—thesis, "Bacillary Dysentery."

LONDON.—Mr. Fisher, President of the Board of Education, has stated, in reply to a question asked in the House of Commons relating to the offer of the Bloomsbury site to the University of London, that when the time comes for King's College to move from the Strand to Bloomsbury, the Government is prepared to seek authority to purchase, at a fair valuation, the buildings at present occupied by King's College in the Strand, and the price so paid will be available towards the cost of the new buildings to be erected for King's College on the new site.

SHEFFIELD.—Dr. R. B. Wheeler has been appointed to the recently established chair in fuel technology, and Mr. Douglas Knoop to that of economics.

SIR JESSE BOOT has made a gift of 50,000*l*. to University College, Nottingham, in aid of the development of the scheme for a University of Nottingham. 30,000*l*. is for the building fund and 20,000*l*. for the foundation of a chair of chemistry.

THE council of University College, Swansea, has made the following appointments to headships of departments, viz.:—*Professor of Metallurgy*: Prof. C. A. Edwards. *Professor of Chemistry*: Dr. J. E. Coates. *Professor of Physics*: Dr. E. A. Evans. *Professor of Mathematics*: Lt.-Col. A. R. Richardson. *Lecturer in Geology*: Dr. A. E. Trueman. *Lecturer in History*: Mr. E. Ernest Hughes.

THE Trustees of the Beit Fellowships for Scientific Research, which were founded and endowed in 1913 by Sir Otto Beit to promote the advancement of science by means of research, have recently elected Mr. [illegible] Hogan to a fellowship. Mr. Hogan was educated at the Catholic University School, Dublin, 1907–15, and has been a student at the University College, Dublin (National University of Ireland), from 1915 to date. Mr. Hogan will carry out his research at the Imperial College at South Kensington.

THE Industrial Fellowship System for the promotion of industrial research, originated by Prof. Robert Kennedy Duncan, has been in successful operation in the University of Pittsburgh since September, 1911. Full particulars of the system are given in a pamphlet by Mr. T. Ll. Humberstone published by the Board of Education. The seventh annual report of the Mellon Institute, founded in the University in 1913, states that the total funds contributed by industrial firms for the nine years ending March 1, 1920, was 1,213,425 dollars, and that in the year 1919–20 the number of fellowships was 47 and the number of fellows 83, the fellowships being 35 for individuals and 12 for groups of workers. A list of fellowships in operation at March 1, 1920, is published, which shows the great diversity of subjects of industrial research to which the scheme has been applied. The fact that the resources of the institute are fully used, and that applications exceed the available accommodation, is convincing evidence of the soundness of the principles on which the system is based. The institute is administered by the director, Dr. Raymond F. Bacon, assisted by an associate director and three assistant directors, who prepare schemes of research work, select the fellows, and supervise their investigations.

THE foundation-stone of the new buildings of the University College of Swansea was laid by his Majesty the King on Monday, July 19. A magnificent site of forty-five acres in Singleton Park, on the shores of Swansea Bay, has been presented to the college by the Corporation of Swansea, which has also granted the temporary use of Singleton Abbey for the housing of the faculty of arts and the administrative offices of the college. It should be a matter of encouragement to the council of the college that the main features of its policy received marked approval and support in the terms of the King's reply to the address of welcome on Saturday last. It is the natural ambition of Swansea to build up a strong School of Applied Science, including a department of metallurgy of the first rank. At the same time the educational ideals of the Welsh people demand for the great population of this industrial district the fullest provision for the study of the humanities and for the advancement of learning in the widest sense. The authorities of the college are fully alive to the magnitude of their opportunities and the greatness of their trust. Unmistakable proofs have already been given by representatives of all classes of deep interest in the work of the college and a determination to secure practical assistance. The wide publicity afforded by the Royal visit and the statesmanlike terms of the King's address cannot but serve to widen and strengthen both enthusiasm and practical support. The concluding terms of the King's reply to the address of welcome were as follows:—"Efficiency is much, but it is not all. We must never forget that education is a preparation for life, and that its true aim is the enlargement of the human spirit. It will be the task of your college to send out into the world men and women fully equipped for the material work which awaits them, and with minds attuned to high ideals, opened to the rich and varied interests of modern life, and steadfastly set towards the service of their fellows."

Societies and Academies.

EDINBURGH.

Royal Society, June 7.—Prof. F. O. Bower, president, in the chair.—D. **Balsillie**: The intrusive rocks of the Dundee district. These belong to two types, viz. diabases and felsites. The former are generally fine-grained dark masses that contain hypersthene and free quartz, which minerals, along with monoclinic pyroxene and abundant plagioclase felspar (60 per cent. anorthite), occur in a highly felspathic ground mass. Hornblende, biotite, iron ores, and apatite occur as accessories, the first-mentioned, however, only rarely. Occasionally free quartz disappears, the place of hypersthene being then taken by olivine. As a type of olivine diabase may be cited the large intrusive mass near Newton, west from Auchterhouse station. The hypersthene diabases are characterised by the presence of acid segregation veins that often show beautiful graphic intergrowth of quartz and felspar. Nearly all these basic rocks are much altered, the phenomenon of albitisation being of frequent occurrence, and typically displayed in the diabases of Castle Huntly, west from Dundee. The pink rocks would probably have been classed by the older writers as mica oligoclase porphyrites, which name still sufficiently describes them. Reference was also made to an outcrop of highly solidified ash occurring at Mill of Mains, north of Dundee, that probably marks the site of an old volcanic vent. In discussing the age of the intrusions, the opinion was put forward that these rocks of the Dundee district should be regarded as belonging to the volcanic cycle of Lower Old Red Sandstone times.—F. L. **Hitchcock**: An identical relation connecting seven vectors.

June 21.—Prof. F. O. Bower, president, in the chair.—J. **Goold**: The musical scale. The author described a new way of regarding the genesis of the musical scale. Beginning with the four notes, or with the three perfect fifth intervals determined by the four notes F, C, G, and D, the author showed that the group of four notes a major third above these, and the third group of four notes a major third below them, gave, when reduced to the range of one octave, all the notes of the recognised chromatic scale. Another point emphasised was that all the notes of the scale had relative frequencies which depended on powers and products of the numbers 3 and 5.—J. **Marshall**: A law of force giving stability to the Rutherford atom. It was shown that if the law of force between a positive nucleus and a negative electron were of the form

$$\frac{1}{r^2}\left(1-\frac{b^{n-2}}{r^{n-2}}\right)$$

a value of n can be found which will preserve the stability of a group of electrons not exceeding seven in number. Since b is small compared to the radius of an atom, this law is indistinguishable from the inverse square law for distances large in comparison with the radius of the atom. If in the case of an atom built up of a series of rings of electrons the tentative assumption be made that the inner rings act on the individuals of the outer rings as if the inner set were replaced by an equivalent charge at the centre, the investigation may be generalised to include such cases also; and it is found that for displacements perpendicular to the plane of the orbit the configuration is unstable when the number of electrons in the outer ring exceeds seven. This would seem to indicate that the atom could be built up of a series of rings of seven electrons, and that we should expect a periodicity in the chemical properties of the atoms corresponding to Mendeléeff's classification, which was stated by Newlands in 1864 in the form: "The eighth element starting from a given element is a kind of repetition of the first."—Prof. A. W. C. **Menzies**: The explanation of an outstanding anomaly in the results of measurement of dissociation pressures.—Prof. J. A. **Gunn** and Dr. D. G. **Marshall**: The harmala alkaloids in malaria.

PARIS.

Academy of Sciences, July 5.—M. Henri Deslandres in the chair.—A. **Lacroix**: An eruption of the Karthala volcano at Grand Comore in August, 1918. This eruption commenced with a quiet flow of lava; a fortnight later explosions commenced, with emission of ashes reaching a great height. The explosive emission is considered as being probably due to the action of superficial water.—Em. **Bourquelot** and M. **Bridel**: The biochemical preparation of cane-sugar, starting with gentianose. Experiments made in 1910 indicated the probability of cane-sugar being one of the products of emulsin on gentianose, but the sugar could not be isolated. In 1920, using emulsin specially purified from traces of invertin, after separation of the glucose as β-methylglucoside, saccharose was obtained in a pure state.—A. A. **Michelson**: The application of interference methods to astronomical measurements. A development of a method described in the *Philosophical Magazine* in 1896. Measurements on Capella made with the 250-cm. reflector at Mount Wilson Observatory gave the parallax of this star as slightly under 0·050″, with an accuracy of about 1/1000th of a second of arc. Experiments at Mount Wilson on a larger scale are contemplated.—W. **Kilian** and P. **Fallot**: The existence of the facies of various Jurassic layers in the province of Tarragon (Catalonia).—A. **Righi**: Observations concerning a recent note on Michelson's experiment. An adverse criticism of some calculations by M. Villey.—W. **Sierpinski**: The measurable B ensembles.—E. **Cartan**: The projective applicability of surfaces.—E. **Berger**: The production of chlorides with a primer.—M. **Godchot**: The oxidation of coal. The experiments described afford no support to the view recently put forward that the oxidation of coal results from the action of bacteria pre-existing in the coal.—E. E. **Blaise**: The action of substituted hydrazines upon acyclic 1:4-diketones. A study of the reaction between dipropionylethane and phenylhydrazine. Substituted hydrazines give pyrrol derivatives with 1:4-diketones.—M. **Delépine**: Ethylene sulphide, C_2H_4S. Previous attempts to prepare the sulphur analogue of ethylene oxide have been unsuccessful. It can be obtained by the action of sodium sulphide upon ethylene chlorothiocyanate, $CH_2Cl{\cdot}CH_2{\cdot}CNS$, and subsequent distillation in a current of steam. Ethylene thiocyanate, $CNS{\cdot}CH_2{\cdot}CH_2{\cdot}CNS$, can replace the chlorothiocyanate in this preparation.—J. **Bougault** and P. **Robin**: The iodoamidines. Benzamidine with iodine and dilute soda solution gives the compound $C_7H_7N_2I$, in which the iodine is attached to a nitrogen atom, since it is quantitatively removed by potassium iodide in acid solution. The reaction appears to be a general one for amidines.—M. **Guerbet**: A reaction for benzoic acid based on its diazotisation: its application to toxicological detection of atropine, cocaine, and stovaine. The reaction is based on the production of β-naphtholazobenzoic acid, and will detect readily 0·1 milligram of benzoic acid.—P. **Idrac**: Convection currents in the atmosphere in their relation to hovering flight and certain forms of clouds.—P. **Nottin**: The absorptive power of earth for manganese. When manganese solutions are treated with soil, manganese is fixed and some lime

is found in solution. Calcite was proved not to react with manganese salts, but lime was dissolved from aragonite and manganese retained.—M. **Galland**: A race of wallflowers with multiple and hereditary anomalies.—A. **Marie** and L. **MacAuliffe**: Study of 344 gypsies. An anthropometrical comparison with the French race.—E. **Roubaud**: The mode of action of powdered trioxymethylene on the larvæ of Anopheles. Further details of the best method of using trioxymethylene for the destruction of mosquito larvæ.—J. **Dufrenoy**: The excretion of vital colouring matters and degenerescence in Ascidians.—E. **Chatton**: A morphological and physiological xeno-parasitic complex: *Neresheimeria catenata* and *Fritillaria pellucida*.—R. **Combier**: The purification of sewage by activated sludge.—A. **Mayer**, L. **Plantefol**, and A. **Tournay**: The physiological action of symmetrical dichlorodimethyl ether.

CAPE TOWN.

Royal Society of South Africa, May 19.—Dr. A. Young in the chair.—J. **Moir**: Colour and chemical constitution. Part xi.: A systematic study of the brominated phenolphthaleins regarding the relation between position and colour. The spectra of twenty-three bromine derivatives of phenolphthalein are described, these being selected from the 658 possible isomers so as to give clear evidence of the value of each of the twelve possible positions for bromine as regards change of colour. These values are tabulated, whereby any of the uninvestigated isomers should be calculable. Phenolphthalein differs from benzaurine in not having a negative paraposition; hence the author concludes that the current chemical formula for the former is incorrect, and suggests a new formulation.—J. R. **Sutton**: The relationship between cloud and sunshine. A brief discussion of the observations of sunshine and cloud made during the twenty years 1900–19 at Kimberley. In a general way much sunshine postulates little cloud; but the relation is not intimate, and a sunshine recorder cannot be regarded as an automatic device for determining the cloudiness of the sky. August gets the most sunshine and February the most cloud.—Miss Ethel M. **Doidge**: The haustoria of the genera Meliola and Irene. The fungi belonging to the genus Meliola are true parasites, sending haustoria into the cells of the host. The most common type is that which has a fine filament penetrating the cuticle and a small globular, thin-walled, uninucleate vesicle in the epidermal cell. Certain species penetrate through the epidermis, through sclerenchyma cells, if these are present, into the first chlorophyll-containing cells of the mesophyll. The haustoria cause a considerable disorganisation of the cells into which they penetrate, and the mycelium completely blocks many of the stomata.

SYDNEY.

Linnean Society of New South Wales, May 26.—Mr. J. J. Fletcher, president, in the chair.—Dr. R. J. **Tillyard**: The Neuropteroid insects of the Hot Springs Region, New Zealand, in relation to the problem of trout-food. Examination of the contents of trout-stomachs showed that the most abundant foods were the green manuka-beetle, *Pyronota festiva*, the larvæ of caddis-flies of the family Leptoceridæ, and a small mollusc, Potamopyrgus sp. Less abundant were larvæ of dragonflies, mayflies, stoneflies, other families of caddis-flies, etc. Since the introduction of the trout the insect fauna of the region has been very greatly reduced, the percentage reduction being estimated as follows: Mayflies, more than 50; stoneflies, 80; and caddis-flies, 90. In the vicinity of a few streams to which the trout have no access insects are still comparatively very abundant. Suggestions for improving the position are made along two lines: (1) Improvement of the food-supply, and (2) reduction in the number of trout.—Dr. R. J. **Tillyard**: The Panorpoid complex. Additions to part 3. Additional evidence is brought forward from the study of the pupal tracheation of *Morova* (*Siculodes*) *subfasciata*, Walk., to support the conclusion that it is unlikely that any existing Heteroneurous type represents even a close approximation to the original archetype of the Rhopalocera.

WASHINGTON, D.C.

National Academy of Sciences (Proceedings, vol. vi., No. 1, January).—C. **Barus**: An example of torsional viscous retrogression. Observations interesting in their bearing on Maxwell's theory of viscosity.—C. M. **Myers** and C. **Voegtlin**: The chemical isolation of vitamines. The method eliminates purines, histidine, proteins, and albumoses, leaving a liquid that can be crystallised, and probably contains histamine or histamine-like substances. The physiological action of the active fractions resembles that of extracts from the mucosa of the small intestine when the intestinal and yeast extracts are purified in the same manner.—C. G. **Abbot**: A new method of determining the solar constant of radiation. A method using the pyranometer applicable on many more days than the old method, and having the advantage that several independent observations of the solar constant may be made on a single day.—F. G. **Benedict**: The basal metabolism of boys from one to thirteen years of age. A formula and a curve are given, and it is shown that, although age and stature as well as body-weight must be considered in predicting heat output for adults, it is not necessary to consider more than the body-weight in the case of boys—a fact probably due to the close correlation between the changes in age, weight, and stature for boys.—R. A. **Dutcher**: The nature and function of the antineuritic vitamine. A general review of the theory, with numerous references, is followed by a brief sketch of the author's work, suggesting that the hormone supply is dependent upon the vitamine-content of the food.—H. F. **Osborn** and C. C. **Mook**: Reconstruction of the skeleton of the Sauropod Dinosaur Camarasaurus, Cope (Morosaurus, Marsh); and W. K. **Gregory**: Restoration of Camarasaurus and life-model. A restoration both in the articulature and in the musculature, with a brief statement of the essential characteristics of each.—W. D. **Matthew**: Plato's Atlantis in palæogeography. It is suggested that the present conformation of the Atlantic bottom dates back, in part at least, to the Palæozoic era.—A. A. **Noyes** and D. A. **MacInnes**: The ionisation and activity of largely ionised substances. A general discussion, with considerable bibliography, leading to the conclusion that most of the largely ionised inorganic substances at moderate concentration may be considered as completely ionised, and the decrease in the conductance-ratio wholly attributed to the decrease of ion mobility, and the change in activity-coefficient entirely attributed to some unknown effect of a physical nature.—A. C. **Lunn**: The commutativity of one-parameter transformations in real variables. A proof previously given by Lie and Engel applicable to analytic functions is supplanted by a proof assuming the existence of continuous first partial derivatives only.—D. L. **Webster**: The intensities of X-rays of the L series. II.: The critical potentials of the platinum lines. After a discussion of the special apparatus employed, a discussion of the lines observed places six lines in L_1, six in L_2, three in L_3. The faint lines of Dershem and Overn are unassigned.

Critical points and intensity ratios are discussed.—J. B. **Murphy**: The effect of physical agents on the resistance of mice to cancer. The evidence points to the lymphoid tissue as an important agent in the immunity reaction of transplanting cancer of mice.—H. C. **Sherman**: The protein requirement of maintenance in man. For the maintenance of healthy men and women an intake of not more than 35–45 grams of protein per "man" of 70 kg. per day is sufficient even when the protein is not especially selected, and hence the "standard" allowance of 1 gram of protein per kg. of body-weight per day provides an ample margin of safety.—R. P. **Cowles**: The transplanting of sea-anemones by hermit crabs. A study of behaviour with the problems it presents in this particular case.—J. A. **Anderson**: Spectra of explosions. Discussion of a new method for obtaining intense spectra of short duration, the new source of light being of the order of one hundred times the brilliancy of the sun.—Report of the Autumn Meeting: The report contains items of business, including the award of medals, the distribution of research grants, and the list of papers read before the Academy.

THURSDAY, JULY 29, 1920.

A Chemical Service for India.

THE constructive proposals put forward in the Report of the Indian Industrial Commission, 1916–18, presided over by Sir Thomas Holland, were dependent on the acceptance of two principles: (1) That in future Government must play an active part in the industrial development of the country, with the aim of making India more self-contained in respect of men and material; (2) that it is impossible for Government to undertake that part unless provided with adequate administrative equipment and fore-armed with trustworthy scientific and technical advice.

The Report under consideration [1] is the work of a Committee which sat in Simla, from February 16 until February 28 of this year, after the president with two members of the Committee had toured through the provinces. The Committee was appointed "to formulate proposals for the organisation of a Chemical Service for India and for the location and equipment of research laboratories."

Prof. J. F. Thorpe, professor of organic chemistry in the Imperial College of Science and Technology, London, was president of the Committee. His associates were Dr. K. S. Caldwell, principal of Patna College; Mr. R. W. Davies, district and sessions judge, North Arcot, Madras Presidency; Dr. W. Harrison, Imperial agricultural chemist, Research Institute, Pusa; Sir P. C. Rây, professor of chemistry, University College of Science, Calcutta; Dr. J. L. Simonsen, forest chemist, Forest Research Institute and College, Dehra Dun; Dr. J. J. Sudborough, professor of organic chemistry, Indian Institute of Science, Bangalore.

The terms of reference to the Committee were:

(1) To consider whether an all-India Chemical Service is the best and most suitable method of overcoming the difficulties and deficiencies pointed out by the Indian Industrial Commission.

(2) In the event of the Committee approving the principle of an all-India service, to devise terms of recruitment, employment and organisation; to indicate the extent to which chemists already in Government employ should be included in that service; and to suggest what should be the relations of the proposed organisation with the public and with Departments of the Government of India and of Local Governments.

(3) In particular to frame proposals for the location, scope and organisation of institutions for chemical research.

During his tour Prof. Thorpe became satisfied that the development of the chemical industries of India could be adequately realised only through the agency of an efficient Government Chemical Service. Nowhere did he find an effective organisation to co-ordinate the various efforts which were being made; not one of the provinces had even formulated a programme of its requirements or decided what educational methods were necessary to attain the desired ends. To achieve success the proposed Chemical Service must be recruited mainly from Indian sources: the question of an adequate training in Indian universities is therefore vital. This subject is specially dealt with by Prof. Thorpe in an able introductory note: the Committee expresses itself as in agreement with his views.

The evidence put before the Committee was so definitely in favour of a Chemical Service that it came to the conclusion that question No. 1 of its remit, quoted above, could be best answered by the formation of a service having as its primary objective the encouragement of industrial research and development.

The Committee makes thirty-five recommendations of which the first twelve are as follows:—

(1) That a Chemical Service should be constituted.

(2) That the service should be called the Indian Chemical Service.

(3) That the service should be controlled by a Director-General.

(4) That a Central Imperial Chemical Research Institute should be erected at Dehra Dun under the Director-General of the Chemical Service, as Director, assisted by a number of Deputy Directors.

(5) That each Deputy Director should be in charge of a separate Department and that, in the first instance, there should be four Departments, (*a*) Inorganic and Physical Chemistry, (*b*) Organic Chemistry, (*c*) Metallurgical Chemistry, (*d*) Analytical Chemistry.

(6) That a Provincial Research Institute under

[1] Report of the Chemical Services Committee, 1920. (Simla: Government Central Press.)

the control of the Local Government should be erected in each province near the chief seat of industry in that province and that each Provincial Research Institute should be under a Director of Research.

(7) That the functions of the Central Imperial Institute should be as follows:—

(*i*) to create new industries and to carry out the development of new processes up to the "semi-large" scale or further if necessary,

(*ii*) to investigate those problems of a fundamental character, arising from the work of the Provincial Institutes, which have been transferred to the Central Institute by the Local Director of Research in consultation with the Director-General. Such problems will be those which have no apparent immediate practical importance but which, in the opinion of the Director-General and the Director of Research, are likely to lead to discoveries of fundamental industrial importance affecting the industries of the country generally,

(*iii*) to assist in the co-ordination of the work in progress in the provinces: both by means of personal discussion between the officers of the Central and Provincial Institutes during the course of the tours made by the Director-General and the Deputy Directors and by means of periodical conferences of Provincial and Imperial officers,

(*iv*) to carry out such analytical work as may be required and to correlate the methods of analysis in general use throughout the country,

(*v*) to maintain a Bureau of Information and Record Office,

(*vi*) to issue such publications as are considered necessary.

(8) That the functions of the Provincial Research Institutes should be as follows:—

(*i*) to maintain close touch with the works chemists and with the works generally and to work out any problems which may be submitted to them,

(*ii*) to develop and place on an industrial scale new industries which have been previously worked out on the laboratory and "semi-large" scale by the Central Imperial Institute,

(*iii*) to carry out such other work as may be necessary to establish and foster new industries peculiar to the province,

(*iv*) to carry out such analytical work of a chemical character as may be required in the province,

(*v*) to erect and control sub-stations in such parts of the province as the development of industry may require.

(9) That, under (8) (*i*) above, arrangements should be made by which a firm supplying a problem should have the use of the solution for an agreed period of time prior to its publication.

(10) That members of the service should be lent to private firms as occasion demanded and should during the period of their service be paid an agreed sum by the firms.

(11) That the Research Institutes should not undertake manufacture in competition with private enterprise but that chemical industries developed in accordance with (8) (*ii*) above should be handed over to private firms as soon as practicable.

(12) That, whenever necessary, experts should be employed to establish chemical industries based on known processes.

Among the other recommendations are that agricultural chemists should not at present be included in the service; that a Ministry of Science should be created as soon as practicable; that a Chemical Survey of India should be carried out at the earliest possible moment; and that the Government of India should give maintenance and equipment grants to students, to enable them to undergo the training in chemical research required for recruitment.

It is not a little remarkable that the only member of the Committee to take exception to the creation of an all-India Chemical Service is the one Indian member, Sir P. C. Rây. A separate note is appended to the Report in which he forcibly states his objections. Sir P. C. Rây's opinion must carry great weight, not only on account of his long experience and his distinction as a teacher and investigator but also because of his familiarity with industrial requirements and possibilities, he having long been concerned with the management of a chemical works which he was instrumental in establishing. The present writer had the opportunity of visiting this works when in Calcutta in November, 1914, and was much struck by the ingenuity displayed in the construction of the plant; various heavy chemicals were being made, including sulphuric acid, in substantial quantities.

Although Sir P. C. Rây considers that the days of Government services are over and that the development of industries by the agency of a Government service is not the most suitable way of dealing with the problem, yet he agrees that, if a Government service be constituted, the proposals of the Committee represent the best method of constituting and carrying on such a service. His view is that better results would be obtained by improving the teaching of chemistry in the Indian universities; by attracting brilliant young men by the offer of research scholarships; and by attaching technical institutes to each university.

The circumstances of India are so entirely

peculiar that it is impossible to judge the scheme from an ordinary point of view. A number of those who contributed to the recent correspondence in NATURE appear to fear that the liberty of the subject engaged in research work may be improperly interfered with and curtailed by the institution of a separate Chemical Service. This should not be the case. It is to be supposed that the studies undertaken will be strictly utilitarian in character—the primary objective being the encouragement of "industrial research" and to secure the co-operation of science and industry. The fact is, the term "research" were better put aside altogether in the present connection—it now has so many meanings, if any meaning in particular: it should be confined to strictly original inquiry and regarded as a word of sacred import. Organised scientific inquiry into industrial problems is what is aimed at by the promoters of the scheme: therefore Central Scientific Institute would be a better title than Central Research Institute, "Research" being a word unknown to the multitude and one for which it never can have any feeling.

India is a country of vast size and is broken up into an infinitude of small holdings: its problems are more than numerous: the nature and extent of its raw materials must be surveyed without loss of time: very little has been done to develop industries. The one crying need seems to be an organisation of effort. A service is required if only in protection of the workers.

Perhaps the chief objection to be taken to the scheme is its magnitude and therefore its costliness; it involves the simultaneous establishment of so many district institutes, to satisfy the desire of the several provinces to exercise administrative control in their own areas. The real difficulty will be to find men who are competent to act as directors—men who are not only technically competent but also sufficiently imaginative and broad in outlook, *able to hold their own socially* and to manage men. Such men have been in constant demand here of late and too rarely forthcoming. Indeed, the complaint is frequent that, though those entering technical careers may be chemists by training, they lack initiative and are unable to shoulder responsibility. Science does not at present attract the right type of intelligence to its ranks. Do not let us delude ourselves into thinking that we can repair our past errors and become a scientific nation at will—by admitting large numbers to the schools and creating numerous new posts: without acumen and experience, nothing can be done. The success of the Indian scheme will depend largely on the man first chosen to fill the post of Director of the Central Institute: he must be gifted with a liberal spirit and with ideas; his time must not be unduly taken up in attending to administrative details; he must himself be a skilled scientific worker. Only such a man will be able to assist the work of the universities and be a generous and capable critic of the men they educate for the purposes of industry and the State service.

Sir P. C. Rây would in all cases start industries by means of technical experts imported from abroad and would not attempt to work them up locally with the aid of the Research Institutes, as proposed by the Committee. He is unquestionably right in so far as large industries, well established elsewhere, are concerned; and as a matter of fact the Committee advises that this course should be taken in all such cases. The proposals of the Committee apply specially to small-scale industries in which it is desirable to encourage native activity; the work done by Sir Alfred Chatterton in Madras in developing the use of aluminium may be quoted in illustration. The Indian is eminently conservative and is not easily persuaded to do new things—but he can often be led by ocular demonstrations; it will be the function of the provincial institutes to give these.

In its reference to the exploitation of forest products, the Committee mentions match-making as an industry which it understands the Forest Department has under contemplation and seems to give its approval. Here Sir P. C. Rây's criticism is to the point. Match-making is so thoroughly understood that it seems undesirable that academic workers should take it in hand: in such a case, it were better at once to call in the expert. The suitability of various fibres for paper-making is quite another question: it is clearly desirable that these should be first tested on the spot, so that the many variations to which the raw material would be subject could be taken into account.

The great value of the Report lies in the recommendation of an all-India scientific service —the directions in which the service can be made of most avail will be gradually discovered as the service comes into operation. That the industrial future of India can be secured only with the aid of the scientific inquirer and by placing industry on a scientific footing is beyond all question. Thanks are due to Prof. Thorpe and his col-

leagues for the able way in which they have dealt with their onerous task.

Mr. Howard, Imperial economic botanist to the Government of India, directed attention recently, at the Royal Society of Arts, to the future of economic botany in India and to the many complex problems awaiting solution: after asking what is the best method of getting such work done—whether we should rely on organisation or trust to the individual—he expressed the opinion that individual action is to be preferred. But surely the competent individual should be able to influence a receptive though unimaginative multitude. Increase in knowledge is of little value if it do not give us an increase of power to use our knowledge—we know that it does. During the war, much organised team work was accomplished by scientifically trained workers under the influence of a few guiding minds. The men who are doing research work in the various schools are for the most part unconscious members of a service acting under the inspiration of a few leaders: there is no reason why the system should not be carried from academic life into the public service. We are alive to the faults by which a public system is likely to be affected and should be able to guard against them.

HENRY E. ARMSTRONG.

Tycho Brahe.

Tychonis Brahe Dani Opera Omnia. Edidit I. L. E. Dreyer. Tomus vi. Pp. v+375. (Hauniæ: Libraria Gyldendaliana, 1919.) Price 19 kr.

MR. HAGEMANN, who is bearing the expense, and Dr. Dreyer, who has undertaken the labour of editing the works of Tycho Brahe, are alike to be congratulated on the appearance of this elegant edition of the first book—the only one ever published—of the "Epistolæ Astronomicæ." The frontispiece consists of a handsome portrait of Tycho Brahe, dated 1586, reproduced from the first edition, which appeared in 1596. Here the portrait is enclosed in an arch ornamented with sixteen coats-of-arms, either, we may conjecture, his sixteen quarterings, or at least the arms of his own and fifteen kindred families. The English reader will note with special interest the arms of Rosenkrans and Guldensteren, and we have not far to seek for bearers of those arms. In Dr. Dreyer's "Tycho Brahe" (1890) Jörgen Rosenkrands is frequently mentioned as a patron of Tycho. He was Governor of Jutland, and in 1588 was made one of the Council of Regency for the young King Christian IV. of Denmark. Axel Guldenstern appears in two letters in the present volume dated 1592, where he is described as a kinsman of Tycho and Governor of Norway.

The letters contained in the present volume range in date from 1585 to 1595. They comprise the correspondence of Tycho Brahe with Wilhelm, Landgrave of Hesse-Cassel, his son and successor Moritz, and his "mathematicus" Rothmann. The letters are partly in Latin and partly in German, but the German letters are always accompanied by a Latin translation. Their contents are well exploited in Dr. Dreyer's "Tycho Brahe," mentioned above, and in his "History of the Planetary Systems" (1906). Perhaps the most generally interesting part of the present collection is the description of Tycho's observatory at Hveen and of his instruments, which occupies pp. 250–95 of this volume. Tycho's attitude to astronomy and astronomers is well illustrated by the selection of eight, whose portraits adorned the crypt of his observatory—Timocharis, Hipparchus, Ptolemy, Albategnius, Alfonso, Copernicus, Tycho Brahe, and Tychonides, with the pithy distichs in which Tycho sums up the importance of each (pp. 274, 275).

The correspondence with Rothmann will remain famous for the clearness with which Rothmann grasped the implications of the Copernican system, and maintained them against Tycho's futile objections, which, to men brought up to believe in a stationary earth, appeared so cogent. It is somewhat pathetic that this record of the ancient controversy should have appeared only a few weeks before the triumphant vindication of a new theory which renders the difference between Copernicus and Tycho meaningless.

Tycho was the first of modern astronomers to make more than occasional observations, and it was therefore natural that the work of the ancient observers, particularly Timocharis, Hipparchus, and Ptolemy, should possess a living interest for him and his correspondents instead of having, as to nearly all modern astronomers, a purely antiquarian importance. Rothmann (p. 115) made one unhappy suggestion about Ptolemy which can scarcely have been intended for publication. Certainly the author can never have dreamed of the way in which it was to be extended. The suggestion is that the places of the fixed stars in Ptolemy were not observed by him, but merely transcribed from Hipparchus. Rothmann shows, quite correctly, that the latitude which Ptolemy professes to have observed for Regulus is inconsistent with the longitude and declination which he also professes to have observed; his own observations, he says, are not inconsistent with

the accuracy of Ptolemy's latitude and longitude; therefore it must be the declination that was in error; this, he thinks, was extrapolated from the declinations observed by Timocharis and Hipparchus, and he concludes that Ptolemy observed no declinations at all, but merely deduced them from Timocharis and Hipparchus. This probably suggested to Tycho Brahe the more sweeping charge, adumbrated in his "Progymnasmata" ("Opera," ii., 151), and stated clearly in the introduction to his Catalogue ("Opera," iii., 335), that the whole of Ptolemy's Catalogue was merely a reproduction of the Catalogue of Hipparchus, reduced to Ptolemy's epoch by means of a constant correction to the star places. This charge has had a wide currency, but has been refuted by Laplace and Ideler, and finally by Dr. Dreyer in his paper, "On the Origin of Ptolemy's Catalogue of Stars," Monthly Notices of the Royal Astronomical Society, lxxviii. (1918), pp. 343–49. The absurdity of Rothmann's original charge may be shown by a computation of the position of Regulus for the epoch of Ptolemy's tables. Ptolemy's declination, as it happens, is correct, but his latitude is in error, and his longitude is greatly in error, doubtless because his tables gave a false longitude to the sun, with which Regulus was compared.

J. K. FOTHERINGHAM.

Psychological Tests in Industry.

Employment Psychology: The Application of Scientific Methods to the Selection, Training, and Grading of Employees. By Dr. Henry C. Link. Pp. xii+440. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 10s. 6d. net.

EXPERIMENTAL psychologists in this country have always been keenly interested in research into individual mental differences, but to America we must turn for the first attempts to apply psychological tests to vocational selection and guidance. As might have been expected, an alternative method has arisen which claims to judge special abilities, aptitudes, and characters by the methods of phrenology, the colour of the hair and eyes, the texture of the skin, the slope of the handwriting, the squareness or roundness of the face, the shape of the chin, etc. As Dr. Link points out, attempts have been made to transform this method into "a reliable and scientific method of character analysis. . . . This so-called science has received wide publicity and has been accepted [both in America and in this country] by many prominent and hard-headed business men. It attempts to place observation on a scientific basis by assuming that certain observable physical characteristics are identified with certain definite mental qualities, and by asserting as a corollary that a visual observation and measurement of the physical characteristics enable the observer to gauge a person's mental, moral, and emotional qualities. The smattering of scientific phraseology in the presentation of this method is just sufficient to impress those who have only a superficial knowledge of the scientific facts involved. . . . The fundamental assumption on which the so-called science of observation rests is an assumption entirely unwarranted by the facts" (pp. 240, 241).

Contrast with this the methods of industrial psychology. The psychologist first "finds, by means of an experimental process, what the relevant activities in an occupation or an operation are." This he does by means of tests which are tried out on workers whose ability is known and with whose work success in the tests can be compared and correlated. In this process he also discovers the standard which ought to be reached in the significant tests by those who wish to succeed at the kind of work in question. He then standardises the manner in which these tests should be used, so that every applicant for a particular kind of work will be examined in exactly the same way, and his ability determined according to the same formula (p. 249).

As Prof. Thorndike indicates in his introduction, "Dr. Link's book is important because it gives an honest impartial account of the use of psychological tests under working conditions in a representative industry. He has the great merit of writing as a man of science assessing his own work, not as an enthusiast eager to make a market for psychology with business men. Indeed the story of his experiments is distinctly conservative . . ." (p. x). They included the testing of girls and men, of clerks, stenographers, typists, and "comptometrists," of machine operators, apprentice tool-makers, etc. They show what a wealth of valuable information for vocational guidance they can afford, and how excellent a corrective they are to the vague, inaccurate knowledge too often possessed by the foreman of the relative abilities of those who work under him. The tests used are fully given in an appendix to the book. The volume clearly indicates the importance of employment psychology, alike to the employer who "wishes to obtain the best possible kind of human material," and to Labour if it "wishes to carry out collective bargaining, if it wishes to base its claims for individuals on the sound basis of ability and training" (p. 389).

Cultivation of the Vine in America.

Manual of American Grape-growing. By U. P. Hedrick. (The Rural Manuals.) Pp. xiii+458+xxxii plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 15s. net.

THIS book is one of the series of rural manuals edited by Prof. L. H. Bailey, and it should prove of great use to both commercial and amateur grape-growers. The opening chapter, dealing with the "Domestication of the Grape," is especially interesting. There are about fifty named species of the grape, most of them found in temperate countries. Of the Old World grapes only one species, *Vitis vinifera,* is cultivated for fruit, but of all grapes this is of greatest economic importance. *Vitis vinifera* is the grape of ancient and modern agriculture, and is the chief agricultural crop of Southern Europe and of vast regions in other parts of the world. The written records of its cultivation go back five or six thousand years, while the ancient Egyptians are known to have grown the vine for wine-making; the methods and processes of domestication, however, are now unknown. The records of the New World yield information on the cultivation of wild species of grapes, and the author describes the domestication process of the four species now extensively cultivated.

The author states that "few other agricultural industries are more definitely determined by environment than the grape industry," and he describes the grape regions of America, discussing the factors which determine the suitability of a region for grape-growing. Climate is the chief of these factors, and is dealt with in detail. Other factors treated of are soil, insects and fungi, accessibility to markets, etc.

Full information is given on propagation, fertilisers, breeding, etc., as well as a chapter on the various operations involved in transferring the grapes from garden to market, together with advice on the carrying out of these operations. The important subject of grape pests and their control is dealt with, the life-histories of the several pests being given in so far as they bear on the control methods.

A particularly interesting chapter is that on "Stocks and Resistant Vines," where we are given an account of the root-louse Phylloxera. This pest made its appearance in France in 1861, and increased so rapidly that by 1874 the whole vine industry of Europe was threatened with ruin. The situation was saved by the realisation of the fact that American grapes did not suffer from Phylloxera attacks, hence the European vines were saved by grafting them on the Phylloxera-resistant roots of American grapes.

The chapter on grape botany gives the general botany of the vine and also includes a detailed account of the American grape species, while in the chapter on varieties of grapes descriptions are given of a large number of different types with their respective characteristics and advantages, the varieties described being those which will appeal to the amateur as well as to the commercial grower. The book is well supplied with illustrations and figures.

V. G. JACKSON.

Our Bookshelf.

Ministry of Public Works, Egypt: Zoological Service. Hand-list of the Birds of Egypt. By M. J. Nicoll. (Publication No. 29.) Pp. xii+119+31 plates. (Cairo: Government Press, 1919.) Price P.T.15 (3s. 6d.).

AN up-to-date treatise on the avifauna of Egypt has for some time past been a desideratum in ornithological literature. It is now forty-eight years since the late Capt. Shelley's well-known book, hitherto the foremost on the subject, appeared, and much has been added to the knowledge of the subject in the meantime. This want is well supplied in an epitomised form by Mr. Nicoll's book.

The author, a well-known ornithologist, has resided in the country for thirteen years, and during the whole of this period has specially devoted himself to the study of its avifauna. The result of his labours is highly to be commended to the bird-loving visitor to Egypt, and to all who are interested in Palæarctic ornithology, to whom, indeed, it is indispensable. The ornis of the "Land of the Pharaohs" is not only rich in its numbers—Mr. Nicoll treats of as many as 436 forms—but also of great interest, since its native birds, though Palæarctic in the main, comprise a number of Ethiopian representatives. Another notable feature is presented by the birds of passage, vast numbers of which bi-annually traverse the country, especially the Nile valley, *en route* to northern summer haunts in spring, and again in autumn on their return to their accustomed tropical, equatorial, and South African winter quarters.

Among the native birds the ostrich became extinct seventy years ago, and it is sad to learn that the characteristic and beautiful Egyptian plover has practically ceased to exist. On the other hand, several once declining species, among them the buff-backed heron, are increasing in numbers as the direct result of protection. In addition to giving the status of the species and sub-species known to occur in Egypt, and particulars on the dates of the coming and going of the migrating birds, the author has furnished a short and useful diagnosis of each bird.

The book is illustrated by a series of thirty-one plates, eight of them in colour and devoted to figures of the protected species, while the rest are black-and-white figures showing the differences between the various species of chats, and certain warblers and wagtails, occurring in the country.

Investigations in the Theory of Hyperion. By Dr. J. Woltjer, jun. Pp. iii+71. (Leyden: E. J. Brill, 1918.)

THE motion of Hyperion, the seventh satellite of Saturn, is of special interest from the commensurability of its period with that of Titan, the two being in the ratio of 4 to 3. The late Prof. Newcomb wrote an important paper, "On the Motion of Hyperion: a New Case in Celestial Mechanics." The present work carries the investigation some steps further. The differential equations are broken up into partial systems, giving the inequalities proportional to the successive powers of e' the eccentricity of Titan's orbit. Newcomb had regarded this development as impracticable, but the present work demonstrates the contrary. The development is at present carried only to the first power of e', which suffices to give a close approximation to the observed inequalities. For example, the ratio of masses of Saturn and Titan is deduced as 3986, which is close to the values 4172, 4125 found by Eichelberger and Santer respectively. Incidentally, we may note that the mass of Titan is about twice that of the moon, and two-thirds that of Mercury. Also the coefficient of the large inequality that depends on Titan's eccentricity is found as 12·96°, not differing much from the value 14·0° found by H. Struve from observation.

The researches made by Dr. Woltjer form a useful step in the attainment of a complete theory of Hyperion's motion, and it is to be hoped that he will himself continue the work, carrying it far enough to include all sensible terms.

A. C. D. CROMMELIN.

A Field and Laboratory Guide in Physical Nature-study. By Prof. Elliot R. Downing. (The University of Chicago Nature-study Series.) Pp. 109. (Chicago, Illinois: The University of Chicago Press; London: The Cambridge University Press, 1920.) Price 1 dollar net.

AT first sight it is difficult to decide whether the book was written for children or for adults—in its assumption of previous knowledge it is hopelessly above the one; in its treatment it is far beneath the other. The preface explains that it is meant for pupil teachers. Directions are given for the making of model aeroplanes, the spinning of tops, etc. But if a youth has missed these delights in his childhood, it is of little use for him to try to find them later on. In training a student to teach children there is no need to treat him as a child himself. Nevertheless, the book is full of good ideas, and many who would find it almost intolerable to use as a laboratory manual would be well repaid for time spent in reading it through.

Genera and Species.

WHEN Linné introduced the practice of giving a generic and specific name to each living organism he probably did not anticipate that the number of names required would run into millions, and with the multiplication of genera and species now encouraged by naturalists some other system of distinction seems desirable.

Of the five or six thousand stars visible to the naked eye only a few have been named, and the rest have to be content with identification by their constellations and by a letter or number.

Something of the same sort might be done for the organic world. The conspicuous and typical examples might retain their names, while both to these and to the remainder a letter or number might be allotted.

If the numbers followed the chronological order in which the species were discovered or first properly described, a catalogue formed on these lines would in itself convey valuable information.

Identification by number or symbol would act as a check to the coining of many barbarous words, and also to the annoying repetition of the same specific names in different genera. All true classification should be genealogical—that is, it should depend on the ancestry of the organism classified. Existing knowledge is insufficient to achieve such an ideal result, but any system not founded on pedigree is open to the objection of not being "natural."

There are often great doubts as to where varieties end and species begin, and where such doubt exists it would, in general, be safer to assume that differences are varietal until it has been found by trial that continued interbreeding tends to produce sterility.

I am informed by authorities well acquainted with the West Indies that this is what happens when half-breed is crossed with half-breed, but not when half-breed mates with white (or better, with black). So far as this evidence goes, it points to something approaching a specific difference between the white and the negro, and many species have been determined on a worse foundation.

Books on special branches of natural history, while giving some sort of description of the various genera and species, do not (there are a few honourable exceptions) indicate, or indicate very imperfectly, the grounds on which the generic or other distinctions rest, and it is not uncommon to find differences between admitted varieties of the same species exceeding those between species reputed to be separate.

To find the reasons for these apparent anomalies by consulting the original papers involves the expenditure of much time and trouble, but the information might be compressed into a small space if properly tabulated.

The Cluster Pine.

Pinus pinaster was probably introduced into Madeira about thirty years before the beginning of the nineteenth century—a hundred years too late to save from wanton extinction the forests of mountain laurel, Cerasus, Persea, juniper, and many a species exclusively Madeiran.

There is a settled method of cultivation. The steep hillsides, ridge, and valley, after the yearly autumn

rains, are made ready to receive the seed which in November and December is scattered broadcast, mixed with wheat and lightly covered over after heavy rain. The green seedlings appear in a few weeks, but there is no tangible development until the wheat is taken away and the decaying stalks have become available as plant-food, and perhaps advantageously helped by a thin surface-dressing of sawdust.

A Pinaster plantation soon becomes productive, yielding in the first years substantial bedding for cattle and, mixed with dried gorse bushes, excellent material for the ovens in the village bakehouses. In four or five years the crop will yield abundantly supporting stakes, 6–8 ft. long, for the climbing beans on which the Madeira peasant so largely depends for his winter food, and, yearly afterwards, sturdy poles in ever-increasing dimensions for the construction of the fascinating trellises in the famous vineyards at a lower level. In twelve or fifteen years the trees have attained the stage of firewood, and, with the exception of a few selected pines left for timber, the ground is once more cleared for planting afresh. The tree-stumps are mostly grubbed up, but those left quickly decay in the ground, and the Pinaster throws up no fresh shoots after cutting. The young Pinaster has a distinct tap-root, but the roots of the mature tree spread in a superficial mat, twining fantastically along the surface among the protruding rocks. In digging the foundations of a lofty tower I met with no roots deeper than 4 ft.

No attempt has hitherto been made to deal with the abundant store of turpentine and resin with which in this region the Pinaster is endowed; and up to the present time the plantations have not suffered from the blights and diseases to which the species is subject elsewhere.

Much Pinaster seed is imported from Portugal, as less costly than collecting locally, but the full-bodied, delicately winged seed from a mature tree is in every way preferable, and to procure it a young, supple-limbed mountaineer will not hesitate over the perilous ascent of the huge trunk, bare of branches 70–80 ft. from the ground. A frail ladder made of ivy-stalk serves his purpose, pegged by segments into the crevices of the rough bark, and on reaching the first horizontal branch the intrepid fellow will pass down a string to a companion and draw up a long pine sapling, and with this, clambering out upon the branch, he will beat down the cone clusters with their prolific crop. Once in three or four years sufficient cones have developed to tempt the climber to this giddy and blood-curdling enterprise, and the seeds are beaten out in a few days when the sunshine has sufficiently opened the cones. The seeds then become the property of the pine steeplejack, the handsome, cinnamon-coloured cones, with the substantial residuum of unextracted seeds, remaining with the landowner.

Pinaster timber of mature growth is a handsome and useful wood, though more difficult to work than the imported deals from America and Norway. I possess some substantial floors which show no signs of decay after thirty years' service.

For general purposes Pinaster is far the most serviceable conifer yet seen in Madeira, and its quick growth, its prolific yield of cones and seeds, and its hardy nature and easy cultivation have given the species a popular pre-eminence which is well established.

Thirty years ago I introduced *Pinus insignis* and made important plantations. One or two of these trees, now twenty-seven years old, stand more than 100 ft. high, with a sturdy corresponding bulk, constituting, with their longer, softer, light green, three-sheathed needles, a handsomer and more attractive form than seen in the Pinaster. But though of equally rapid growth, the cultivation requires more care than the Pinaster; neither is the tortuous-fibred wood regarded with favour by the working carpenter.

P. pinaster, *P. canariensis*, and *P. insignis* all hold their cones for indefinite periods, but the Himalayan *P. longifolia* sheds all its produce in September, leaving nothing but the embryonic promise of next year's crop, the substantial development of the large cones with their resinous, club-ended bracts occupying only seven months.

I cannot close this account without a reference to *Cupressus macrocarpa* and *C. goveniana* as recent accessions of great promise to the Madeira show of conifers; and some mention is also due to the Douglas fir, *Taxodium sempervirens*, etc., stately examples of which adorn our mountain-gardens.

Madeira, June 29. MICHAEL GRABHAM.

The Training of Practical Entomologists.

THE increasing demand for fully trained economic entomologists was, I think, evident to all who followed the proceedings of the recent Imperial Entomological Conference held in Burlington House. We are faced with the difficulty of ensuring an adequate supply of keen and experienced young men fitted for service in India, the Soudan, and other of the British dominions wherever the requirements may be greatest. The solution of economic problems in entomology is far more difficult than is commonly supposed, and only men of the broadest biological training, coupled with the gift of imagination, are likely to achieve results of lasting value to the community. Under present conditions they are frequently called upon to take up responsible positions after inadequate training and with only a modicum of practical experience. In the training of an economic entomologist two obvious pitfalls have to be avoided: one is a too exclusively academic or laboratory experience, while the other is a too specialised training in economic entomology at the expense of the necessary preliminary grounding in general biology.

The majority of practical entomologists become attached to an agricultural department, a smaller number enter a forestry department, and it is evident, therefore, that they need to acquire some knowledge of the principles and practice of either agriculture or forestry. The time at a student's disposal is an important factor, and the majority of men can usually only devote four years to training prior to turning out and earning their living. Let us take, for example, the course of a student at Cambridge. If he possesses good abilities, he should be able to take Part I. of the Tripos at the end of the second year and obtain his preliminary grounding in biology and chemistry, and I would suggest that the remaining two years should be devoted to entomology *plus* agriculture. The diploma course in agriculture might well be modified to suit such students, allowing them to devote as much time as possible to entomology, and confining the agricultural training, so far as may be feasible, to a knowledge of the soil and crop cultivation, omitting the greater part of the course dealing with stock and animal nutrition. In so far as entomology is concerned, I would advocate the first year (or the student's third year) being devoted entirely to what may be termed the scientific side of the subject. The second year (or the student's last year) should be given to as full a training as possible in economic entomology with the necessary field work. He should be given every opportunity for observing the common pests in the field and the methods of dealing with them. I strongly advocate every student also being given an independent piece of life-history work to

follow out, in order to acquire methods of accurate observation and technique. This work should be written up and modelled in the form of a scientific paper, and illustrated so far as may be desirable. By means of such an essay the student will become familiar with the elementary procedure in research work, he will acquire some power of independent observation, and learn how to deal with entomological literature, thus gaining some idea of the sources where he will find first-hand information.

Furthermore, I would also insist upon the student forming a small but thoroughly representative collection of insects, so proving that he has had some field practice in collecting, and is able to refer them to their families and genera. By means of such a course as I have outlined, it should be possible to train good, all-round entomologists, capable of tackling a problem unaided when out in the wilds of Africa or the plains of India.

If the student can spare a fifth year, it would be all to his advantage, and the time would be most profitably spent in prosecuting some line of independent entomological research. A. D. IMMS.

Institute of Plant Pathology, Rothamsted Experimental Station, Harpenden.

The Separation of the Isotopes of Chlorine.

IN order to prevent confusion of issues, instead of Cl and Cl′ let us write A and B. Then when we say that A and B are identical, we mean that all the properties of A and B are the same except that of position occupied. Thus we are enabled to divide the atoms into two groups, the A group and the B group, in spite of their identity of properties. Then it is quite certain that if the atoms exist as molecules A_2, B_2, and AB, in equilibrium by the reversible reaction $A_2+B_2 \rightleftharpoons 2AB$, the equilibrium is given by $[AB]^2/[A_2][B_2]=K=4$.

The following considerations will, I think, meet any difficulties that have been raised in reconciling this reaction with Nernst's heat theorem. In the case of complete identity, if we convert the solids A_2 and B_2 into the solid AB by evaporation to the gases A_2, B_2, transformation into the gas AB, and condensation to the solid AB, we obtain an increase of entropy of $R\log 4$. But this solid is really a solid solution or mixture, since, as we assumed that the vapour pressure over it is equal to the pressure over the solids A_2 or B_2, we must assume that the molecules condense on its surface with "longitudinal indifference." The solid, then, is a solution of the molecules AB in BA.

Now the entropy of a body consists of two parts, one depending on the distribution of velocities, the other on the distribution of the co-ordinates of position. The first term cannot give rise to any change of entropy when the solids are transformed, irrespective of Nernst's theorem, but the second term is a constant, and accounts for the change of $R\log 4$. It may, in fact, be calculated directly by statistical methods.

If we assume that the gas AB condenses to the solid AB (or BA) instead of into the solid solution, then we must take the pressure over this solid as double that over A_2 or B_2, and not equal to them; because, consistently with the assumption of the formation of the pure solid AB, we must assume that the solid rejects half the molecules which strike its surface; that is to say, the molecules AB condense, but not the molecules BA.

This double vapour pressure will make the entropy of the two gram-molecules of AB (or BA) equal to the entropy of one gram-molecule of A_2 *plus* one gram-molecule of B_2.

No essential difference in the argument is made when A_2 differs slightly from B_2.

Prof. Soddy throws out a suggestion for the removal of the term $R\log 4$ which surely must be erroneous. He seems to agree to the distribution of molecules given by $[AB]^2/[A_2][B_2]=4$ (which must result whatever kinetic process be assumed), but he considers it wrong to write 4 as the equilibrium constant of the reaction $A_2+B_2 \rightleftharpoons 2AB$, as this gives for the coefficients of the reaction velocities $k_1=4k_2$. He therefore would write the reaction $A_2+B_2=AB+AB$, and then, taking half the concentration of AB, write $[\frac{1}{2}AB][\frac{1}{2}AB]/[A_2][B_2]=K=1$. Therefore $k_1=k_2$.

To write this reaction in this form is unjustifiable. In the first place, that $k_1=4k_2$ in no way contradicts the assumption of the identity of A and B. For the velocity coefficients do not depend only on the properties of the atoms or molecules involved, but contain a factor depending on the statistics of the reactions. In this respect the direct and reverse reactions may be different. This is better seen by comparing the two reversible reactions $2A=A_2$ and $B+C=BC$, where A, B, and C are identical atoms. The two reverse coefficients are equal, $k_2=k_2'$, but the two direct coefficients are not equal, for $k_1=\frac{1}{2}k_1'$. This is because n atoms B, together with n atoms C, give twice as many B–C collisions as n atoms of A give A–A collisions. If we write the reaction $A+A \rightleftharpoons A_2$, and take half the concentration of A, we still do not find $k_1=k_1'$, but $k_1=2k_1'$.

In the second place, to write the reaction $A_2+B_2 \rightleftharpoons AB+AB$ suggests that we can divide the molecules AB into two equal sets, and that a significant collision only occurs when an AB molecule from the first set collides with an AB molecule from the second set. Finally, the semi-permeable membrane that may be used in calculating the change of entropy due to the gaseous reaction must be assumed permeable to all or none of the molecules AB, thus giving an entropy change $R\log 4$. So that by no considerations whatever are we justified in taking half the concentration of the AB molecules when calculating the change of entropy. ANGUS F. CORE.

The University, Manchester, July 24.

Anticyclones.

PROF. HOBBS in NATURE for July 22 gives some experimental reasons for contending that over large ice-covered areas, such as exist in Greenland and the Antarctic continent, the cooled lower layer of air moves outwards in all directions from the centre of the ice-covered area. Under the influence of the earth's rotation the air thus set in motion is regarded as circulating as in normal anticyclones, and Prof. Hobbs on that account speaks of such areas as being anticyclonic. He remarks: "The centrifugal nature of this motion tends to produce a vacuum above the central area of the ice mass, and the air must be drawn down from the upper layers of the atmosphere in order to supply the void. It is here that is located the 'eye' of the anticyclone." He thus postulates an anticyclone with a *low-pressure centre*.

With the physics of Prof. Hobbs's theory there need be little criticism. The point really seems to be: Are the conditions described by him as existing over an ice-cap anticyclonic? An anticyclone has a high-pressure centre, and a cyclone a low-pressure centre, the surface air moving outwards in the former and inwards in the latter, whereas the conditions described by Prof. Hobbs are an *outward flow* and a *low-pressure centre*. Would it not be well to designate such conditions by some other word? R. M. DEELEY.

Tintagel, Kew Gardens Road, Surrey, July 23.

Solar Variation and the Weather.

By DR. C. G. ABBOT, Director, Smithsonian Astrophysical Observatory.

NEARLY a century ago three pioneers, Sir John Herschel, Pouillet, and Forbes, laid the foundations of the measurement of solar radiation. Each devised an instrument for measuring the heating effect of the solar rays and used it diligently. Pouillet and Forbes availed themselves of the law of extinction of light, which had been independently discovered about 1760 by Bouguer and Lambert, to calculate the intensity of the solar rays, as they would be outside our atmosphere. Forbes's researches in the Alps proved that this law is not strictly applicable to the sun's rays as a whole, and he was led to believe that the value of the so-called solar constant of radiation was as high as 2·85 calories per sq. cm. per min. Pouillet's value, based on the assumed validity of the Bouguer-Lambert law, was 1·76 calories.

As pointed out by Radau, the problem of estimating the intensity of the solar heat outside our atmosphere requires the study of the various spectrum rays separately, because their transmission through the atmosphere is unequal. Langley invented the spectro-bolometer about 1880, and immediately applied it to the problem as analysed by Radau. In the famous Mount Whitney expedition of 1881 Langley carried on spectro-bolometric and pyrheliometric measurements simultaneously at an altitude of 12,000 ft. Misled by certain theoretical considerations, however, these experiments seemed to him to yield the value 3·07 calories per sq. cm. per min. as the most probable value of the solar constant of radiation. A correct reduction, which he also gave in his report, yielded 2·22 calories. Later experiments made on Mount Whitney and on Teneriffe indicate that while the spectro-bolometric work was good, Langley's pyrheliometric determinations were too high, so that the true result should have been 1·9 calories.

Up to that time no fully satisfactory instrument for measuring the intensity of solar heat at the earth's surface had been perfected. About 1893 Prof. Knut Ångström's highly ingenious electrical compensation pyrheliometer fixed the scale of solar radiation measurements surely within 5 per cent. In recent years the accuracy of the Ångström pyrheliometer has reached to 2 per cent. or better. In 1913 three independent series of determinations at the Smithsonian Institution fixed the standard scale of radiation measurements now generally adopted. The Ångström scale as corrected by A. K. Ångström lies 1·8 per cent. lower.

At Washington, under Langley's direction, the spectro-bolometer, which at the time of the Mount Whitney expedition was almost unmanageable, was perfected in the decade 1890–1900 into a tractable, trustworthy instrument, and made to trace photographically an autographic solar spectrum energy curve extending from wave-length 0·3 micron to 3·0 microns within 10 minutes.

In the autumn of 1907 experiments were begun in Washington to fix a standard procedure for solar constant observations. Omitting minor details, the process which resulted is as follows: Beginning when the sun is near 15° above the horizon, about six solar spectrum energy curves, and simultaneously pyrheliometric measurements, are made, ending when the sun's altitude has reached about 60°. These curves are measured at about forty points corresponding to known wave-lengths from far in the ultra-violet to far in the infra-red. Taking each wave-length by itself, these intensities on the six separate curves follow the Bouguer-Lambert law of extinction. Hence plotting the logarithms of measured intensities as ordinates and corresponding values of the secants of the solar zenith distances as abscissæ, each group of six points determines a straight line. Producing this line to zero of abscissæ—that is, to the line corresponding to no atmosphere at all—we read there the logarithms of the intensity for the various wave-lengths, as the energy curve would be found outside our atmosphere—on the moon, for instance. The scale of energy in calories per square centimetre per minute comes by comparing the total area included under the spectro-bolometric curves with pyrheliometer readings taken simultaneously. Such, in brief, is the process.

Determinations were begun at Washington in October, 1902. In the springtime of 1903 a large drop amounting to nearly 10 per cent. was found in the values after the end of March. The changed values persisted so steadily that we were led to entertain the hypothesis that the solar radiation had actually diminished. A comparison was made between solar heat and terrestrial temperatures. It actually appeared that just after the apparent drop in solar radiation there occurred a general drop in terrestrial temperatures for all available stations of the north temperate zone. This led us to the long campaign of solar radiation observations which I shall now describe.

In 1905 we began sending yearly expeditions to observe solar radiation at Mount Wilson, California, also the seat of the famous Mount Wilson Solar Observatory of the Carnegie Institution. I am happy to acknowledge the great assistance and enthusiastic interest which Dr. Hale and his colleagues have at all times given our work there.

From the first the Mount Wilson values, though far more accurate than Washington values, owing to the clearer and more uniform sky conditions of California, showed on their face a variability over an extreme range of 10 per cent. in the emission of solar radiation. The sun appeared to be a variable star having a twofold type of variation: First, a fluctuation with the march of years attending changes in solar activity as indicated by sunspots, faculæ, prominences, etc.; secondly, a fluctuation running its courses in a few days, weeks,

or months. Both types of variation are highly irregular. The longer-period type appears to reach 4 per cent. for 100 Wolf sun-spot numbers. The shorter-period changes are larger, and often amount to 3 or even 5 per cent. in a week or a fortnight. Sometimes they reach 10 per cent.

In order to test the validity of these apparent solar changes, we secured nearly simultaneous observations at Washington (sea-level) and Mount Wilson (1730 metres). Also in 1909 and 1910 at Mount Wilson and Mount Whitney (4440 metres) close agreement of results was found. Then in 1911 and 1912 we observed nearly simultaneously for several months at both Mount Wilson and Bassour, Algeria (1160 metres). Both Mount Wilson and Bassour indicated a range of solar variation of nearly 10 per cent. The coefficient of correlation between their indications in 1912, according to Mr. Knox Shaw's determination, is $+58 \pm 7{\cdot}9$ per cent. Thus our view of the sun's short-period irregular variation was confirmed by the agreement of these results from two stations separated by one-third of the earth's circumference.

Since then we have confirmed the solar variability in many ways. Most convincing, perhaps, is the variation we have found in the distribution of radiation over the sun's disc attending changes in the solar radiation. As is well known, the sun's centre is brighter than its edges. We find that the contrast of centre to edge changes from day to day and from year to year. These twofold changes run in opposite senses with respect to increased solar radiation, and seem to indicate that the cause of the solar variation of long period is the hotter sun attending increased circulation at sun-spot maximum, while the short-interval changes are caused by changes of transparency of the sun's outer layers.

In 1918 the Smithsonian Institution established a station at Calama, Chile, supposed to be one of the earth's most cloudless regions. We have been disappointed in the degree of cloudlessness, but our young men have observed the "solar constant" there on about 75 per cent. of all days since July 27, 1918. Comparisons with Mount Wilson in 1918 gave a "probable error" for one determination at a single station of 0·0111 calorie, or about 0·6 per cent. The Calama values have ranged from 1·884 to 2·028 calories, or 7 per cent.

Mr. H. H. Clayton, chief forecaster of the Argentine Meteorological Service, has compared all the Mount Wilson and Calama solar observations, 1905 to 1920 inclusive, with the temperatures and rainfall of Argentina. He finds a high degree of correlation between them. The subjoined table shows Clayton's comparison of the average marches of temperature in Buenos Aires for the years 1913, 1914, 1915, and 1918 (1916 and 1917 were not available to him), corresponding to all the occasions when the solar constant values observed at Mount Wilson fell between the stated limits. The deviations of temperature are expressed in tenths of degrees Centigrade, and range from $+2{\cdot}0°$ to $-1{\cdot}5°$ C. from the normal. The extreme and mean results are given also, translated into Fahrenheit, in Fig. 1.

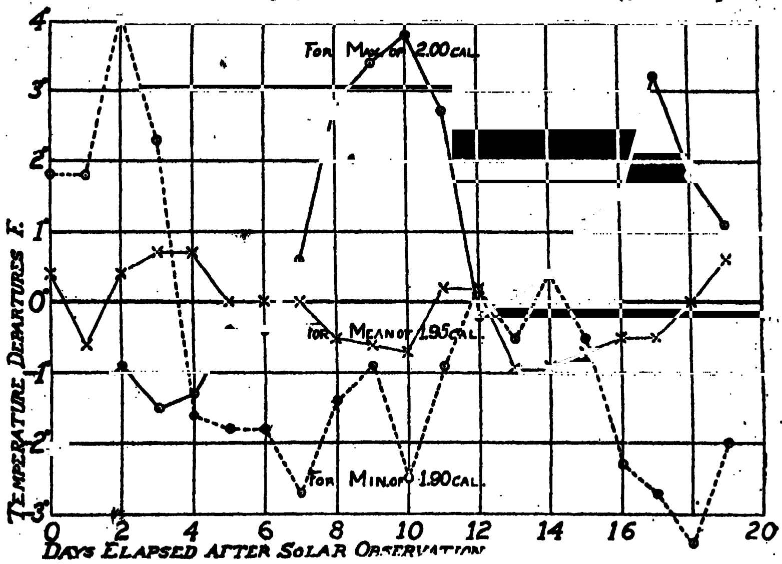

FIG. 1.—The prolonged influence of solar changes on terrestrial temperatures. The three curves show the average march of temperature departures at Buenos Aires, as published by Mr. H. H. Clayton, for nineteen days next following days of maximum, mean, and minimum solar radiation in the years 1913, 1914, 1915, and 1918 for the months May to November. The solar observations were made by the Smithsonian Astrophysical Observatory at Mount Wilson, California, more than six thousand miles from Buenos Aires. The curves marked "Max.," "Mean," and "Min." correspond respectively to mean values of the "solar constant" of 2·00, 1·95, and 1·90 calories per square centimetre per minute.

Derivations from Normal Temperature in Buenos Aires following Different Intensities of Solar Radiation (May to November).

Solar radiation values in gram-calories per cm.² per min.	Days following																		
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
2·000±0·010	−12	−7	−5	−8	−7	−2	−[illegible]	3	15	16	20	14	−1	1	2	6	8	17	10	6
1·980±0·010	−1	−6	−2	−1	−8	0	6	9	9	5	5	4	7	9	5	−1	2	6	0	6
1·960±0·010	2	9	4	0	−2	−2	−2	0	−2	−2	−4	−5	−1	−4	−5	−1	−2	−3	−3	5
1·940±0·010	2	−2	1	7	9	2	2	0	−3	−4	−3	7	2	−5	−5	−6	−3	−3	3	2
1·920±0·010	9	0	−4	−4	−6	−4	−9	−5	−2	0	3	3	5	6	3	−5	−3	−7	−5	1
1·900±0·010	10	10	23	13	−9	−10	−10	−15	−8	−5	−14	−5	1	−3	2	−3	−13	−15	−19	−11

It is very striking that the solar changes produce such large and prolonged temperature effects. On the tenth and seventeenth days after the event the average temperature following solar constants of 2·00 calories differs by more than 6° F. from that following solar constants of 1·90 calories.

The temperatures following minimum "solar constant" values are generally lower than the normal from the third to the nineteenth day; they are above the normal before the third day; while those following high values are above the normal from the sixth to the nineteenth day, they are below the normal before the sixth day; and those corresponding to mean "solar constant" values differ by little from the normal through the whole interval.

The latter state of affairs is probably decidedly

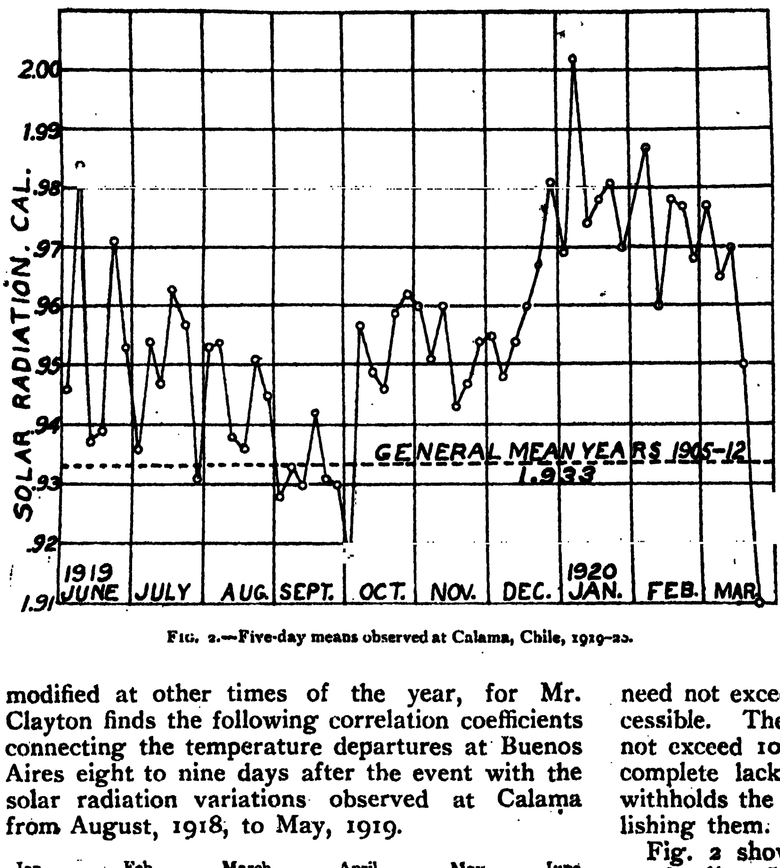

FIG. 2.—Five-day means observed at Calama, Chile, 1919–20.

modified at other times of the year, for Mr. Clayton finds the following correlation coefficients connecting the temperature departures at Buenos Aires eight to nine days after the event with the solar radiation variations observed at Calama from August, 1918, to May, 1919.

Jan.	Feb.	March	April	May	June
−0·49	−0·20	+0·18	+0·23	+0·33	—
July	**Aug.**	**Sept.**	**Oct.**	**Nov.**	**Dec.**
—	+0·20	+0·26	−0·23	−0·29	−0·33

Taking these figures with the figures given above, we are to conclude that while on the first three or four days after the event high solar radiation tends to produce high temperatures in Buenos Aires from October to February, the opposite tendency governs March to September.

These reversals of solar variation effects with the time of the year are paralleled by reversals with geographical position, according to Clayton, who was at first led to regard these geographical reversals as zonal. But it now seems more probable to him, I think, as well as to Nansen, that they are associated with the great atmospheric-action centres rather than with the earth's zones. As these action centres change place from time to time, it seems possible that the geographical and secular reversals merge as effects of one general cause. While it may seem extraordinary at first sight that the past winter has been exceptionally severe (at least in Eastern United States), though solar constant values have been steadily exceptionally high from early in October to February, this may be compared with the known fact that when there are many sun-spots high solar radiation and low temperatures also occur together. Unusual cloudiness or prevailing polar winds may well account for low temperatures associated with high radiation.

Clayton's studies have led him to a system of forecasting in which telegraphic reports of daily solar constant values as obtained by Smithsonian observers at Calama, Chile, take a prominent part. He claims decided and valuable success for both temperature and precipitation forecasts.

If these pioneer results should be confirmed it seems highly desirable to establish several other solar constant observatories in the most cloudless far-separated regions of the earth. By telegraphic communication all their results would be available for daily forecasts all over the world. The cost of such stations fully equipped need not exceed 25,000 dollars for the most inaccessible. The yearly cost of maintenance need not exceed 10,000 dollars. It is now merely the complete lack of funds for the purpose which withholds the Smithsonian Institution from establishing them.

Fig. 2 shows the march of "solar constant" results from June 1, 1919, to March 24, 1920. In no other period since 1903 has there been observed three consecutive months of values so high as those of the winter of 1919–20. The following rapidly falling values accompanied the extraordinary solar and terrestrial phenomena of March 22, 1920:—

Solar Radiation Values of March, 1920.

Date	Mean 11 to 17	18	19	20	21	22	23	24
Value	1·968	1·954	1·940	1·931	1·941	1·927	1·866	1·905

The Earliest Known Land Flora.[1]

By PROF. F. O. BOWER, F.R.S.

THE vegetable kingdom is made up of plants of most varied size, character, and habitat. Comparing those various types, the view becomes ever more insistent that dependence on water is the master-factor determining their existence. As we range their diverse forms according to probable sequences of descent, those which we regard as the most primitive according to their structure and mode of reproduction are those which are habitually the most dependent upon constant water supply. It is the same with the animal kingdom. These broad results were summed up by Weismann some forty years ago in the statement that the birth-place of all animal and plant life lay in the sea. If this be true, it follows that all life on exposed land-surfaces has been secondary, and derivative.

Geologists tell us that from the remote past land-surfaces have stood exposed above the level of the ocean. The continents and islands may have differed from time to time in their outline and area from those of the present day. But we may believe that from a very early period land-surfaces have had a continuous existence, so that life upon land may itself have been continuous from the time when living organisms first emerged from their natal waters. Such beliefs throw back to the very remote past the possible origin of life upon dry land. But still the probability remains that aquatic life antedated that event. These considerations lead inevitably to the questions: When was dry land first invaded from the water? What were the first land-living plants and animals like? And how did they rank as compared with modern life?

Leaving zoologists to solve these questions for their own branch, we botanists are to-day in a better position than ever before to answer them with regard to plants. Though still far from being able to visualise the beginning of the story, recent discoveries have made it possible to see clearly and in detail the nature of the earliest known land flora, which is that of a period older than the Upper Devonian. During recent years fossil plants of early Devonian age have been found in Sweden and in Scotland in greater profusion than ever before, while the Scottish specimens are so well preserved that they are now almost as well known in structural detail as plants of the present day. Already in this room repeated lectures have been given on the Palæozoic flora. Many plants of the Carboniferous Period have been described here in microscopic detail, and they are mostly referable to affinity with such living types as ferns, club-mosses and horsetails. Some, such as the Sphenophylls and Pteridosperms, represent classes which have since died out. But, speaking generally, the flora of the coal is composed of plants comparable with the lower vascular plants now living. They possessed stems, leaves, roots, and sporangia. Some even produced seeds like modern Gymnosperms.

Passing back from the Carboniferous period to the Upper Devonian, the flora, though more restricted, may still be described in terms applicable to the living vegetation. The plants include among others the gigantic fern-like *Archaeopteris hibernica*, from Kiltorkan, co. Kilkenny; the large Lycopod Bothrodendron, from the same source; and the large-leaved Pseudobornia, from Bear Island. Flat leaf-expansions are here seen, and the plants named have been referred in their general characters respectively to affinity with the ferns, club-mosses, and horsetails. But between the Upper Devonian and the strata that lie below geologists tell us that a vast period of time intervened. The evidence of the plant-remains supports this. The earlier Devonian fossils so far known are meagre in number of forms. In their characters they differ more markedly from the plants of the present day than any of their successors. They were rootless, and there appears to be a complete absence of large, flattened leaf-expansions. It is upon them that the new discoveries have shed so interesting a light. Conversely, that light is reflected back by comparison upon the more recent forms. In fact, a new chapter has been opened in plant-morphology, and a new class of vascular plants, the Psilophytales, has been established to receive these representatives of the oldest known land flora. The study of them is leading to new interpretations of the form shown by plants of later periods, and ultimately of the present day.

Until 1913 the plants of the early Devonian rocks were very imperfectly known. Their recognised characters were chiefly negative. There was no evidence of broad leaf-surfaces, nor was it clear whether or not they bore leaves as distinct from stems. The existence of true roots was also doubtful. The best known plants were constructed of approximately cylindrical stalks bearing lateral spines. These stalks arose from a branched and creeping base. Some of them showed crozier-like curves when young, and sporangium-like bodies were sometimes found upon them. The most distinctive of these plants were grouped by Dawson in his genus Psilophyton, and he published a reconstruction of the species *P. princeps*. It was, however, the subject of adverse criticism by his contemporaries, and the validity of the genus was questioned.

It was upon a field so open as this that light has now been shed. From fresh-water deposits of early Devonian age round Lake Röragen, on the frontier between Norway and Sweden, Dr. Halle collected many specimens of fossil plants. But they were mostly impressions, and showed only imperfect preservation of their microscopic

[1] Discourse delivered at the Royal Institution on Friday, April 30.

structure. He distinguished several genera of plants with branched cylindrical stems bearing small thorn-like appendages, and some of them distal sporangia. Many of his specimens were referred to *Psilophyton princeps,* and bore out in the main the reconstruction of Dawson. Halle was able to confirm the existence of a central vascular strand in Psilophyton, consisting of tracheides, a fact which ranks it with certainty among vascular plants of the land. But the most distinctive novelty which Halle discovered in the Röragen beds was a fossil which he called Sporogonites. It consisted of a simple stalk bearing a terminal capsule. From its form, and the character of its contents, he held it to be a sporogonium comparable with that of the Bryophytes; but a generalised type, not referable to any existing group of them. An alternative suggestion was that Sporogonites may represent only the upper part of a more highly developed sporophyte, perhaps on the line of descent of the Pteridophytes. Thus the presence of Sporogonites does not actually prove the existence of Bryophytes as we now know them in the early Devonian rocks. But nevertheless it has a peculiar interest. Hitherto there has been no certain record of the existence of any moss-like type in the Palæozoic period. The demonstration of so moss-like a sporangium as Sporogonites is certainly the most thrilling of the facts brought forward by Dr. Halle.

FIG. 1.—Vertical section through the protocorm of *Rhynia Lignieri* with rhizoids, embedded in peat (×14).

In 1913, three years before Dr. Halle's publication of these discoveries at Röragen, the first of the new observations of early Devonian plants in Scotland was recorded. Dr. Mackie, of Elgin, found at Rhynie, in Aberdeenshire, certain isolated blocks of chert containing plant remains. A little later the source of these blocks was traced to a bed of chert, older than the Upper Devonian, found *in situ* by the Scottish Geological Survey. Its origin appears to have been this. An exposed land-surface existed there in Middle or Lower Devonian time, subject to intervals of inundation. It became periodically covered by vegetation. By decay of its stems and underground parts a bed of peat would be formed. The peat was then flooded, and loose sand deposited over it. Again the vegetation was repeated, and so successive bands were formed to some 8 ft. in thickness. Then followed water with silica in solution, supplied from some fumarole or geyser. The peat-bed was thus sealed up, and the plants preserved with astonishing perfection.

From this bed of chert four distinct vascular plants have been recognised, and described in the minutest detail by Dr. Kidston and Prof. Lang. They are all essentially similar in type, though sufficiently different to be placed in three genera, named respectively Rhynia (two species), Hornea, and Asteroxylon. Rhynia and Hornea are leafless and rootless, while Asteroxylon is also rootless, but it bears leaves of a simple type. The plants thus clearly indicate a primitive state prevalent at that period. They conform in general features to the type of Psilophyton as described by Dawson, and as recognised in greater detail by Halle. But here in the Rhynie chert the structural details are so well preserved that these earliest of all known vascular plants can be examined and described almost as well as any modern living plants. Some have even been found standing erect as in life. Through untold ages, like the legendary Knights of the Round Table, they have thus awaited the revivifying touch of modern science.

Of the four plants so far described from the Rhynie chert, *Hornea Lignieri* is relatively simple. From a distended and lobed protocormous base rose the stems, which bifurcated. These bore

distal sporangia, which represent their transformed tips. Sometimes the sporangia were themselves forked. The protocorm was bedded in the peat, and parenchymatous, with many rhizoids (Fig. 1). The cylindrical stems stood upright from it, and were about 2 mm. in diameter. They were traversed by a simple stele with a solid core of tracheides, surrounded by phloem. The stele forked at the dichotomies of the stem, but stopped short at the base of the sterile columella, which ran upwards into the flat-topped, and apparently indehiscent, sporangium. The latter appears as a transformation of the end of the stalk, which is simply an ordinary branch of the plant. The spores are tetrahedral, as they are in all of these plants of the chert. The general aspect of Hornea is such as to provoke comparison with the Bryophytes, notwithstanding certain strongly divergent characters. This may have some real significance in view of its small size, and relatively simple structure.

Photo] [Dr. Kidston.

FIG. 2.—Aerial stem of *Rhynia major* seen in transverse section (×20).

Rhynia major is larger and better preserved, but still it also is structurally simple. It had a less distended rhizome, from which the robust cylindrical stems arose. These consisted, as in Hornea, of a central stele with solid xylem-core and investing phloem, surrounded by a massive cortex, of which the inner region appears to have been photosynthetic. Outside was a well-marked epidermis with stomata. These and the vascular tissue prove the aerial habit of the plant (Fig. 2). The stems ended in solitary massive sporangia, as much as 12 mm. in length, without a columella, and filled with tetrahedral spores (Fig. 3).

Neither of the species described bore any appendages on its stems. But *Rhynia Gwynne-Vaughani*, though smaller than *R. major*, shows a feature of morphological advance towards something in the nature of appendages. The upright stems bifurcate as before, bearing distal sporangia similar to, but smaller than, those of *R. major*. But near to their base there are "hemispherical projections," apparently of superficial origin. Some of these gave origin to tufts of hair, but others produced adventitious branches, which, having narrow bases, were easily detached, and served as means of vegetative propagation. Though these organs are not easily ranked with those of living plants, they are something in advance of what is seen in Hornea and *R. major*. The sporangia are relatively small, and there is no clear evidence of their dehiscence.

The largest, as it is also the most complex, of these plants is *Asteroxylon Mackiei*. Its base

Photo] [Dr. Kidston.

FIG. 3.—Sporangium of *Rhynia major* filled with spores (×5½).

consisted of branched rhizomes, which burrowed after the manner of Stigmarian rootlets, and each was traversed by a vascular strand with undifferentiated xylem; but curiously enough rhizoids are absent. These rhizomes passed over into upright aerial stems, which attained a diameter of as much as a centimetre, and had a complex structure. They forked, and bore externally small and simple leaves. The stele had a stellate xylem very like some Lycopods. From its rays issued strands passing to the bases of the leaves, but not entering them. As in Lycopodium, more than one vertical series of leaf-traces may issue from each

ray of the stellate xylem, a fact that confirms the Lycopod comparison (Fig. 4). Longitudinal

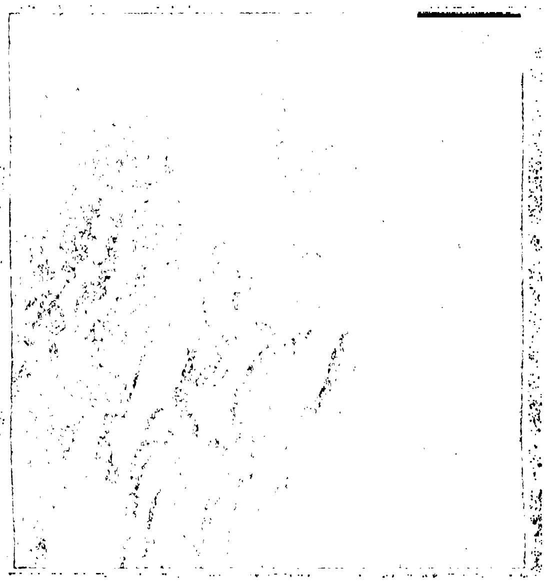
FIG. 4.—Large stem of Asteroxylon cut transversely just below dichotomy, and showing leaves attached externally (× about 10).

sections show the relations of epidermis, cortex, phloem and xylem, and the way in which the inner



Photo] [*Dr. Kidston.*

FIG. 5.—Stoma of *Asteroxylon Mackiei* in surface view (× 210).

cortex of stem and rhizome often contain fungal hyphæ. It is possible that in the rhizome these may have been concerned in mycosliric nutrition. Higher powers demonstrate the tracheides as irregularly, or spirally, barred, but not scalariform. An endodermis has been seen delimiting the cylindrical stele, and mesarch protoxylem is found in the xylem-rays. The leaves are parenchymatous, the vascular strands stopping short at their bases. The epidermis has been found to bear very perfect stomata (Fig. 5). The essential points of structure of the plant are thus fully known.

In certain blocks sporangia have been found attached to profusely dichotomising stalks of simpler structure than the main stems of Asteroxylon, and not definitely attached to them. They are associated, however, with stems of Asteroxylon, while those of Hornea and Rhynia, from which they are structurally distinct, are absent from the blocks. The association makes it probable that these peculiarly forked branches and sporangia really belong to Asteroxylon. The sporangia are relatively small and pear-shaped, and they had a distal dehiscence. The whole plant of Asteroxylon was thus more advanced in various respects than any of the other three plants of the chert.

(*To be continued.*)

Obituary.

Dr. Robert Munro.

We regret to record the death, on July 18, of Dr. Robert Munro, the well-known Scottish archæologist. Dr. Munro was born on July 21, 1835, and was thus within three days of completing his eighty-fifth year. By his death prehistoric archæology loses one of its foremost exponents in this country; but his work will not readily be forgotten.

Munro was educated at Tain Royal Academy and at Edinburgh University. After practising medicine for some years at Kilmarnock, of which town his wife was a native, his increasing interest in archæology led him to retire in 1886, in order to devote himself entirely to research in this branch of science. His name will always be associated in particular with the study of prehistoric lake and pile dwellings, a subject to which his attention was first directed in 1878, while on a visit to Zurich, when he took the opportunity of examining the prehistoric lake dwellings in the neighbourhood. Shortly after his return, the discovery of two canoes and wrought wood by workmen engaged in drainage work on the estate of the Duke of Portland at Locklee, Tarbolton, Ayrshire, suggested the possibility of fruitful results to be obtained from investigations on analogous sites in Scotland.

At the instigation of Mr. R. W. Cochran-Patrick, Munro undertook the exploration of this site, and in the two following years he investigated similar sites at Friar's Carse, Lochspouts, and Buston, all in the south-west of Scotland. Accounts of these investigations were published from time to time in the collections of the Ayrshire and Wigtownshire Archæological Association, and a report on the excavation of the crannog at Friar's Carse appeared in the Proceedings of the Society of Antiquaries of Scotland, of which body Munro had been elected a fellow in 1879. The results were afterwards embodied in "Ancient Scottish Lake Dwellings," published in 1882, a book which, as the author said in his preface, sought "to place before the general reader a record of some remarkable discoveries recently made in the south-west of Scotland in a department of archæology hitherto little known." In addition to giving the results of his own excavations, he summarised the somewhat scanty accounts of previous investigators in this field in Scotland, and the work of Boyd Dawkins and others in England.

After the appearance of this work, Munro's interest turned in an increasing degree to Continental prehistoric sites. Always a great lover of travel—he considered it his only form of recreation—he visited most of the important sites in Europe. Papers dealing with prehistoric remains in Holland, Denmark, Italy, Carinthia, and elsewhere appearing in the Proceedings of the Society of Antiquaries of Scotland and in other publications in the early 'eighties, and a book describing a journey in Bosnia, Herzegovina, and Dalmatia published in 1895, bear witness to the extent of his travels and investigations. The publications of the earlier years were, however, merely a by-product while he was collecting the material for his most important work, "The Lake Dwellings of Europe," published in 1890, of which the substance had been given in his Rhind Lectures, delivered in 1888. In this book Munro made a complete survey of the subject, dealing in particular with the problems of the Swiss lake dwellings and the terramare settlements of Italy. In 1907, seventeen years after its publication, M. Salomon Reinach, in a preface to Modestov's "Introduction à l'histoire romaine," said of it: "Il n'y a qu'un livre récent sur les stations lacustres et les terramares de l'Italie; il a été écrit en anglais par un Ecossais." A French edition appeared in 1908.

The results of subsequent discoveries, and in particular of discoveries on the terramare of Emilia, were embodied in the second part of "Palæolithic Man and Terramare Sites of Europe," published in 1912. This matter had formed the Dalrymple Lectures on Archæology in the University of Glasgow in 1911; while the first part, which summarised our knowledge of palæolithic man at that date, had been delivered as the Munro Lectures in Anthropology in 1912, being the first course after the institution of the lectureship by the University of Edinburgh. In addition to the works already mentioned, Munro was the author of several other books, including "Prehistoric Problems" (1897), "Prehistoric Scotland and its Place in European Civilisation" (1899), "Archæology and False Antiquities" (1905), "Prehistoric Britain" (1914), a popular summary, and a number of papers which appeared at various dates in the Proceedings of learned societies and elsewhere.

In 1886 Munro's freedom from professional duties enabled him to undertake the secretaryship of the Society of Antiquaries of Scotland, an office which he held until 1899. In 1893 he was president of the Anthropological Section of the British Association for the Advancement of Science, and in 1903 he delivered one of the evening discourses at the meeting of the association at Southport. This discourse was published in 1904 under the title "Man as Artist and Sportsman in the Palæolithic Period." In 1894 he was appointed chairman of the research committee instituted in that year to conduct excavations on the site of the lake village at Glastonbury, other members of the committee being Sir John Evans, Gen. Pitt-Rivers, and Prof. W. Boyd Dawkins. More fortunate than two of his famous colleagues, Munro lived to see the completion of this important work in 1907, and continued to act as chairman when the committee's investigations were turned to the Meare lake village. He was part author of the monograph describing the

results of the investigations at Glastonbury, which was published in 1911-12.

The importance of Munro's researches was widely recognised. He was a fellow of the Royal Society of Edinburgh, and an honorary member of the Royal Irish Academy, of the Royal Society of Antiquaries of Ireland, and of the more important anthropological and archæological societies of the Continent.

Munro's work as an archæologist was marked by a cautious reserve and a great sanity in judgment. Yet, on occasion, none could be quicker than he in arriving at a conclusion, which further investigation usually proved to be well within the limits of accuracy. It was characteristic of him that he rarely accepted the results of others without personal investigation, and the great mass of information which he digested and summarised in his published works had been largely tested and checked by his own observations. His thorough mastery of his subject as a practical investigator was suggested even in such a trifle as the way in which he handled a stone implement.

E. N. FALLAIZE.

IRISH education has sustained a severe loss by the death of the RT. HON. W. J. M. STARKIE, Resident Commissioner of National Education. For the past twenty-two years Dr. Starkie guided the rather cranky ship of Irish primary education through the troubled sea of clerical management. After a brilliant school career, he obtained the highest classical distinctions at Cambridge University and Trinity College, Dublin, including the fellowship of the latter college. In 1897 he was appointed president of Queen's College, Galway, but after a brief period of office became Resident Commissioner and *ex-officio* chairman of the Board of National Education. As a member of the Viceregal Commission on manual and practical instruction, he played an important part in framing the scheme of reformation of the aims and methods of Irish education, which later he was called upon to administer. Upon his shoulders rested in large measure the responsibility of effecting the change from a mechanical system of payment by results to an inspection system with a broader view of the functions of a school. Knowing the magnitude of the forces opposed to change, he displayed conspicuous courage in carrying far-reaching reforms to a successful issue. His address on "Recent Reforms in Irish Education" at the Belfast meeting of the British Association in 1902 was a strenuous and courageous exposure of the weaknesses of Irish education; it aroused much bitter criticism from the clerical managers.

Dr. Starkie was also chairman of the Board of Intermediate Education, and thus occupied a unique position in Irish education, which probably owes more to him than to any one man during the last half-century. He was a brilliant essayist and one of the first Greek scholars of his time.

Notes.

AN important statement on the development of the synthetic dye industry was made by the chairman of the Colour Users' Association at Manchester on July 20. Mr. Vernon Clay referred to two very urgent reasons why the dye industry in England should be developed to the very utmost, one being the real necessity that existed from the commercial and industrial side, and the other the necessity from the point of view of national security. Only a country possessing a large dye-making plant which could alternatively be used for the production of the various organic chemical substances employed in war could hope to be in a proper position in any future struggle, for the next war would be essentially a chemists' war, and start on a very large scale. The Government has recognised that for national security it is essential that synthetic dye factories equal to those of any other possible hostile nation shall be in existence, and to further this object the President of the Board of Trade has stated that the pledge to the synthetic dye industry, that the importation of synthetic dyes shall be permitted only under licence, will be given effect to in legislation as quickly as possible. Although the British output of dyes already exceeds the pre-war importation from Germany, there are several important dyes which are not yet manufactured in this country, and a licensing scheme such as is promised appears to be the only proper means of fostering the industry and of encouraging manufacturers gradually to extend their range until the country is absolutely self-contained as regards its production of dyes and the necessary intermediate products.

THE question of the universities and the excess profits duty was the subject of debate in the House of Lords on July 21. By the concession already proposed by the Chancellor of the Exchequer the position is roughly this:—While the excess profits duty will be charged at 60 per cent., the State, as a matter of fact, will bear 12 per cent. of any charitable contributions made by a business firm. Earl Grey, however, in the hope of inducing private benefactors to make larger subscriptions, wished the Government to show more liberality and to consider the *total* remission of the duty so far as it affected the universities. On behalf of the Government the Earl of Crawford could not grant the further concession, but, in the course of his reply, made an important announcement regarding university grants-in-aid. He stated that the Chancellor of the Exchequer was prepared to submit to Parliament an increase of the present vote of 1,000,000*l.* to 1,500,000*l.* in the Estimates for the year 1921–22, and, in addition, to consider the advisability of proposing to Parliament a further non-recurrent sum to assist the universities in meeting the grievance of those of their senior members who were precluded from profiting to the full by the benefits of the federated superannuation scheme of the universities. No pledge was given in either case, and both proposals are subject to the overriding necessities of national finance.

Apparently the consideration of any supplementary grant within the present financial year is not contemplated. While it is reassuring to find that the Chancellor of the Exchequer recognises the clamant needs of the universities, there will be no little disappointment that provision more appropriate to the present needs, especially in the matter of superannuation, is not made.

ON July 21 the King received at Buckingham Palace the principal members of the British Empire Forestry Conference, which sat in London during the preceding fortnight. The members included delegates from Great Britain and Ireland, India, and the various Dominions and Colonies. Lord Lovat, president of the conference and chairman of the Forestry Commission of the United Kingdom, presented the delegates separately to his Majesty; and Mr. H. R. Mackay, Forest Commissioner, Victoria, and representative of the Commonwealth of Australia, read an address to the King, who in his reply congratulated the Home Forest Authority on its joining hands so soon with foresters in other parts of the Empire. He referred to the work of universities and colleges and to the experience gained in the Crown woods and private plantations as having laid a foundation on which it is incumbent to build. The King pointed out the peculiar difficulty of forestry work, which demands, perhaps, more imagination, more patience, and more foresight than any other industry, and considered it an immense advantage that the experience of all parts of the Empire should be brought into a common stock and made available for all. Forestry, directed as it is to checking reckless consumption of the world's supply of timber and to teaching and encouraging thrifty use and prudent replacement, represents a great work for the common good. The conference will result both in practical improvements in the operations of the Forestry Services at home and overseas, and in a truer and wider appreciation of their value to the Empire at large.

WITH the advice and assistance of the U.S. National Research Council, a co-operative body of scientific experts on injurious insects and plant diseases and of manufacturers of insecticides, fungicides, and general chemicals and apparatus used in fighting the enemies of field and orchard crops has just been organised under the name of the Plant Protection Institute. The purpose of the institute is to promote the general welfare by supporting and directing scientific research on the pests of crops, shade trees, and ornamental plants and on the methods of their control, and by furthering co-operation between the scientific investigators and the manufacturers of chemicals and appliances, especially for the sake of effecting standardisation and economy in the production and use of the means of fighting pests. Also it expects to aid in the dissemination of scientifically correct information regarding the control of injurious insects and plant diseases. Much excellent work along this line is now being done by Government and State organisations, but a further advance can be made by introducing a wider co-ordination and co-operation of the efforts of both the scientific men and the manufacturers of control devices. It is in this general direction of co-operative work that the Plant Protection Institute expects to be most active.

Two general excursions, both on Saturday, August 28, have been arranged in connection with the Cardiff meeting of the British Association. One party will drive through the Wye Valley to Tintern, where lunch will be taken; thence to Llanover, where they will be the guests of Lord Treowen for tea (price of ticket 19s.). The other party will cross the Bristol Channel to Weston-super-Mare, and drive to Cheddar, Wells, and Glastonbury, returning to Cardiff by boat in the evening (price of ticket 21s.). Owing to the difficulty of arranging transport, the local secretaries will be much obliged if members intending to join either of these excursions will kindly signify their intention of doing so as soon as possible. Both these are whole-day excursions, and it will be impossible for members to be brought back to Cardiff until rather late in the evening. Letters should be addressed to the Local Secretaries, British Association, City Hall, Cardiff.

THE eighteenth annual meeting of the general committee of the Imperial Cancer Research Fund, held on July 22, of which we publish an account in another column, shows that the Fund has returned to full activity after the interruptions of the war. We are glad to note that our premier organisation for cancer research mainly concerns itself with the purely scientific aspects of the problem. The detailed study of cell-metabolism now in progress, as foreshadowed in the Director's report, should, if energetically pursued, lead to advances in general biology of permanent value, apart from their application to the special problems of cancer. It is gratifying to find that the Fund is again playing its part as a central organisation of international collaboration in cancer research.

THE one hundred and first annual meeting of the Société Helvétique des Sciences Naturelles will be held at Neuchâtel on August 29–September 1. The following are among the papers to be presented:—"Les aciers au nickel dans l'horlogerie," C. E. Guillaume; "Die Vegetation des Diluviums in der Schweiz," Prof. H. Brockmann-Jerosch; "Ueber das Kropfproblem," Prof. Hedinger; "Les fouilles de la Grotte de Cotencher," Prof. A. Dubois; and "Die Gesteinsassociationen und ihre Entstehung," Prof. P. Niggli. Particulars of the meeting may be obtained from Prof. O. Fuhrmann, Université, Neuchâtel, or Prof. E. Piguet, rue de la Serre 2, Neuchâtel.

THE Rayleigh Memorial Committee has decided that the memorial to the late Lord Rayleigh in Westminster Abbey shall take the form of a mural tablet to be erected near the memorials to Sir Humphry Davy and Dr. Thomas Young. The execution of the tablet will be entrusted to Mr. Derwent Wood. It is expected that after all expenses are met there will be a balance remaining, and this the committee proposes shall be used to establish a library fund at the Cavendish Laboratory, Cambridge, with which Lord Rayleigh was closely associated.

THE autumn meeting of the Iron and Steel Institute will be held at Cardiff on September 21–24, under the presidency of Dr. J. E. Stead. An influential reception committee, of which the Right Hon. the Earl of Plymouth has consented to act as chairman, Mr. E. Steer, vice-president of the South Wales Institute of Engineers, as deputy chairman, and Mr. D. E. Roberts as honorary secretary, has been formed to carry out the necessary arrangements.

SOON after the signing of the armistice in 1918 the United States Government sent a Commission to France to investigate the war developments in mining and metallurgy and to observe the methods taken to re-establish the collieries and steel works destroyed by the enemy. Mr. G. S. Rice, chief mining engineer of the Bureau of Mines, was a member of this Commission, and a valuable account of his observations was communicated to the Franklin Institute last December, and is published in the June issue of the Journal of the institute. The descriptions of the mines and the methods adopted in working them are confined mainly to the Pas-de-Calais district, and many views of the destroyed surface works are given. The author is of opinion that the most satisfactory way of reconstructing the mines is to cut up and remove the tangled ironwork at the top of the shafts, which are almost all badly cratered by explosives, and to reline the shafts themselves at those points where they pass through water-bearing strata and where they had in consequence been blasted by the enemy in order to drown the mines. He believes this method will be less costly than sinking new shafts. He has every confidence in the ability of the French engineers to deal successfully with the problem.

IN his report submitted to the joint session of the Oriental Societies at Paris Sir George Grierson describes the progress which has been made in the Linguistic Survey of India. What may be called the Cadastral Survey of these languages is now complete except for the Deccan and for Burma, of which a separate survey is in contemplation. The work so far done includes 179 languages and 544 dialects. The account of the so-called gipsy languages, many of which are secret dialects, is ready for the press. That dealing with the Eranian languages contains much interesting matter, particularly the account of Ormuri, a tongue with Dardic affinities, spoken by a small tribe settled in the heart of the Afghan country. At present Sir George Grierson is engaged upon a comparative vocabulary, representing 168 words—numerals, pronouns, common nouns, and declensional and conjugational forms—giving all the equivalents in all languages which have been studied in the course of the Survey, with a few words in some non-Indian languages, such as Japanese, Chinese, Manchu, Turki, Arabic, Avesta, and Persian. As a supplement to the Survey a number of gramophone records illustrating the pronunciation of various Indian languages is in course of preparation, and these are being distributed to institutions where they will be available for students. The progress made in this great work is thus most important.

AN interesting series of lectures was delivered recently at the London School of Economics and Political Science by Dr. B. Malinowsky, a young Polish anthropologist, who, as a member of the Robert Mond Ethnographic Expedition, spent a considerable time among the people of eastern New Guinea, in particular in the Trobriand Archipelago. Dr. Malinowsky's investigations throw fresh and welcome light on primitive economics. Trade is organised by the influence of the chief, associated with a magician in charge of each department of communal activity. "Primitive economics, as exemplified by the Trobrianders, present a picture different from, and more complex than, that usually assumed. National economy, as a system of free exchange based on untrammelled competition, where value is determined by the play of supply and demand, does not exist. But a system of production, exchange, and consumption does exist, socially organised and subject to definite customary rules. In addition to activities connected with the quest for food, there are many others, such as circular trading and ceremonial enterprise, in which the natives perform organised work, controlled by their conceptions of wealth and value, and therefore distinctly economic. In all these activities there is an interplay of chieftainship, kinship, and social organisation. Ceremonial life, magic, myth, and tribal law control and are controlled by economic elements." Anthropologists will await with interest a full account of this remarkable economic and social organisation. Part of the evidence is summarised in a paper by Dr. Malinowsky, "Kula: The Circulating Exchange of Valuables in the Archipelagoes of Eastern New Guinea," published in the July issue of *Man*.

WHILST the Crocker Land Expedition explored to the north-west of Greenland, the Canadian Arctic Expedition of 1913–18 investigated the district lying east and west of the Mackenzie River. The mollusca the Canadians brought back have now been studied and described by Dr. W. H. Dall (Report Canad. Arctic Exped., 1913–18, vol. viii., part A, 1919, pp. 29, 3 plates). This collection is of special interest, because, save for a partial exploration about 1863 by Mr. R. Macfarlane, of the Hudson Bay Co., the fauna to the eastward of the Mackenzie River delta has remained entirely unknown. It was thought that probably the great outpour of fresh water from the river might have proved a barrier to the passage of marine species from the western Arctic Ocean, and that the eastward fauna would show a considerable infusion of Greenlandic forms. The result of the study of the collection proved otherwise, for of the hundred Arctic species collected over the whole area in question—a collection, therefore, far richer in numbers than that of the Crockford Expedition (see NATURE for July 8, p. 593)—only five were characteristically Eastern Arctic. Apparently the narrow, tortuous, ice-blocked passages which lead to the Greenland seas are accountable for the failure of the Eastern Arctic mollusca to colonise in the Bathurst region, while the open sea to the west readily gives access to the Western Arctic forms. Only six new marine species are established, and these are fully described and

figured. A few fresh-water forms were met with, including a new species of Physa, which is of interest as being the most northern species of the genus. Still, it should be noted that the closely allied *Aplexia hypnorum*, of circumpolar distribution, occurs with it. The Limnæas proved extremely puzzling, and Dr. Dall is inclined to consider that both the form known as *caperata*, Say, and the *vahli* of Beck may be only boreal mutations of the well-known *Limnaea palustris*, Müller. Full lists of all the species collected at the several stations and from Pleistocene deposits are also included in this important paper.

MR. W. WYBERGH has brought forward evidence, including that of marine mollusca, to show that the coastal limestones of the Cape Province (Trans. Geol. Soc. S. Africa, vol. xxii., p. 46, 1920) are by no means entirely due to the cementation of recent dunes. The well-known dune limestone seems to have been formed over and against a more ordinary and shelly marine limestone, which constitutes the true Bredasdorp formation, and is of late Pliocene or Pleistocene age.

PAPERS on the Crown Colony of Sierra Leone are comparatively rare. Mr. F. Dixey (Trans. Geol. Soc. S. Africa, vol. xxii., p. 112, 1920) describes evidences of Pleistocene movements of elevation, with the formation of a coastal plain along nearly the whole coast of the peninsula or Colony proper, merging on the east into low ground that extends far into the Protectorate. Parallel raised beaches show that the uplift was intermittent. The highest beach is some 300 ft. above the sea. Four photographic views accompany the paper.

THE question of the persistence of genera is raised by Dr. C. D. Walcott in describing a remarkable series of floating cyanophyceous algæ from the Middle Cambrian Burgess Shale of British Columbia (Smithsonian Miscell. Coll., vol. lxvii., No. 5, 1919). Morania, one of his new genera, so closely anticipates the structure of the modern Nostoc that only a feeling that they cannot have been fully identical leads the author to propose a new generic name. The illustrations are presumably from photographs of specimens coloured by hand before reproduction; but they are, to say the least, surprising.

MR. LOUIS RENOUF, of the Bute Museum, Rothesay, writing in the *Museums Journal* for April–May on various technical methods, including the mounting of wet specimens under watch-glasses and petri dishes, remarks on the difficulty of obtaining such glasses with even edges, and nicely finished plates on which to mount them. The difficulty led to the discovery that there was "no glass-planing plant in the whole of Great Britain." If this be so, the discovery accounts for a good deal that scientific workers have had to contend with in obtaining glass apparatus (at whatever price) from British firms.

"THE Rainfall in the Island of Formosa" has recently been issued by the Government-General of Formosa, with a summary of meteorological observations at Taihoku and five other observatories. Since the meteorological service was established in 1896 rainfall stations have been added as available from year to year. There were only 28 at the end of 1903, and there are now 135. Every 106 square miles of Formosa has, on the average, one station. Most of them are attached to various Government Departments. At 83 out of the 135 stations records are available for ten years or more. The average annual rainfall over the island is 2486 mm., the greatest fall, 7176 mm., being at Kashoryo, situated on a mountain slope at the head of a valley open to the north-east a few miles south of Kelung; this spot is said to be probably the most rainy in the Far East. The minimum annual rainfall for Formosa is 1050 mm. at Rochikuto, in Taichu, on the west coast. There are two rainy seasons, one during winter along the extreme north coast associated with the north-east monsoon, the other in summer on the mountain districts in South Formosa, largely due to typhoons and thunderstorms. Typhoons occasion a considerable variation in the rainfall according to their track and proximity, the track being usually from south-east to north-west. The heaviest rainfall in twenty-four hours in Formosa is given as 1034 mm. at Funkiko on August 31, 1911, which is the same day as that of the flood in Taihoku shown in the frontispiece of the publication under notice. The heaviest of the excessive rains in different parts of the world, quoted for comparison, are Charra Ponjee, India, 1036 mm., June 14, 1876, and Baguio, Philippines, 1168 mm., July 14, 1911. Comprehensive tables and maps are given showing the monthly and seasonal mean rainfall and the number of rainy days, also the five-day mean rainfall at six observatories from the results for twenty-two years, and the diurnal range, intensity, and duration of rain.

WE have received copies of the second biennial Hurter and Driffield memorial lecture delivered by Prof. Alex. Findlay before the Royal Photographic Society on May 11, and the Hurter memorial lecture recently delivered by Mr. F. F. Renwick before the Liverpool Section of the Society of Chemical Industry. Prof. Findlay discoursed on the properties of colloids in general, and especially with reference to photographic processes and materials. He says: "In the production of the photographic plate, . . . from the moment of mixing the solutions to the final stage of ripening of the emulsion, we have a complex series of changes taking place in a delicately balanced and complex colloidal system, in which coagulation, peptisation, solution, and adsorption doubtless all take part. . . In the production of the latent image . . . it seems probable that we are again dealing with phenomena of adsorption." Mr. Renwick deals with three characteristics of the latent image: "(1) The possibility of physically developing an image on a fixed and washed plate; (2) the possibility of transferring and subsequently developing (both physically and chemically) latent images from the silver salt in which they are formed to another, by changing the former chemically into a less soluble silver salt; and (3) the destructibility of the latent image by the further action of light itself under certain conditions." He gives the details of some

very interesting experiments of his own, and concludes that in the "most highly sensitive photographic plates we are dealing with crystalline silver bromide in which, besides gelatine, some highly unstable form of colloidal silver exists in solid solution, and *that it is this dissolved silver which first undergoes change on exposure to light*." He finds a reasonable explanation of solarisation "by assuming a peptising action on the part of the later-formed chemical products of light action (bromine, hydrobromic acid, etc.) with formation of a photohalide relatively rich in dissolved silver, but almost undevelopable."

A NEW radio call signal used by the Post Office is described by Major Shaughnessy in the *Electrical Review* for July 16. Until recently one of the drawbacks to radio reception was that it was always necessary for an operator to be listening, as there was no method of making the received signals operate a loud calling device. There are many outlying small radio stations in this country in islands and lightships the number of calls on which is so small that it would not justify the expense of having an operator always in attendance. The Post Office, by using a simple valve amplifier, a Turner thermionic relay, and a retardation device in series, has successfully employed the weak radio currents to ring a bell. In order to call the station a long "dash" of 15 seconds duration is sent. During this time a condenser at the receiving station is slowly charged through a 3-megohm resistance. After about twelve seconds the condenser is practically fully charged, so that when the signal ceases and the tongue of the relay moves back to the spacing stop the discharge of the condenser deflects a second relay, and this causes a bell to ring. This condenser device has been used by the Post Office for several years on land lines to call the operators, and is found to be very efficient. Trials of the set have proved that it is practically impossible for "jamming" or atmospheric disturbances to actuate the apparatus. It has been fitted on the P.O. cable ship *Monarch*, and even with heavy "jamming" has proved successful up to a hundred miles. This calling device can be applied for sending the distress signal at sea known as the S.O.S. signal. It will obviously extend the use of radio communication to much smaller ships than at present, as the saving of operators' wages considerably reduces the cost of maintenance.

Two recent articles in the *Engineer* (July 2 and 9) describe at some length the hydro-electric power works at the Great Lake, Tasmania, which is situated approximately at the geographical centre of the island at an altitude of 3350 ft. above sea-level. From the southern end of the lake the River Shannon finds an outlet some two miles west of the bed of the River Ouse, and the two streams flow in fairly parallel courses for some distance. But the fall of the River Ouse is much more rapid than that of the River Shannon, with the result that, while at a point opposite the middle of the lake the Ouse has an elevation of 120 ft. above it, a few miles south the Ouse has fallen to considerably more than 1000 ft. below the Shannon. A short connection between the two rivers at this point enables a very high head of water to be obtained. For the initial installation only the water from the Great Lake catchment area has been utilised, but it is now in contemplation to divert the head-waters of the Ouse into the lake, and by this means a total capacity of 70,000 h.p. will be available at the turbine shafts. The dam across the southern end of the Great Lake, which at present impounds the water to a height of 11 ft. above the sill, will be raised to give an effective height of 40 ft. The existing power station at Waddamana contains two 5000-h.p. and two 8000-h.p. turbines, all of the Boving type; three more 8000-h.p. machines are under construction, and will shortly be installed. In order to develop the total fall a second station will be formed at a higher level, where a head of 250 ft. is available and a serviceable capacity of 12,000 h.p. is at present running to waste.

WE notice that, in consequence of the continued increased cost of production, the published price to non-fellows of the society of the Journal of the Royal Society of Arts has been raised to 1*s*.

MESSRS. R. AND J. BECK, LTD., 68 Cornhill, London, E.C.3, inform us that they have obtained a supply of mounted specimens of the scales of the Test Podura, *Lepidocyrtis curvicollis*, which is recognised as being one of the best tests of high-power microscope object-glasses. These scales have been for long unobtainable, and the new supply will be welcomed by many microscopists.

THE research on automobile steels carried out by the research committee of the Institution of Automobile Engineers has now been brought to a successful conclusion. It is hoped that the report, which was approved at a meeting held on July 21, will be ready for issue by about the end of August, when a further announcement in regard to price, etc., will be made.

THE "Rough List" (No. 359) of books on natural history just issued by Messrs. Bernard Quaritch, Ltd., 11 Grafton Street, W.1, will be of interest to collectors of first and rare editions, for among the thousand or so volumes offered for sale are many treasures. There is also a good sprinkling of ordinary editions listed at low prices. Practically the whole ground of natural history is covered by the catalogue; there are, besides, sections on mathematics, mineralogy, palæontology, and physics.

A BULLETIN issued by the Department of Industries, Madras, entitled "The Manufacture of Glue in the Tropics from Tannery Refuse," was noticed in NATURE of February 5 last, p. 611. The director of the Department now informs us that the pamphlet has been placed on the market so that the information contained in it may be widely known. The pamphlet is priced at 1 rupee, and copies can be purchased from the Superintendent, Government Press, Mount Road Branch, Madras.

Our Astronomical Column.

THE DATE OF EASTER.—It seems a curious anachronism that our calendar in the twentieth century should still be largely influenced by the lunar chronology which passed out of direct use nearly two thousand years ago. That was the most obvious system to employ at the dawn of astronomy, the moon's rapid motion and the ease of locating its position in the heavens making it far superior to the sun as a time-measurer. But as time went on the inconvenience of having a variable number of months in the year, and of having events like the equinoxes and solstices occurring on variable dates, caused the system to be abandoned and a purely solar calendar substituted.

The Passover was, of course, on a fixed date of the lunar calendar, the fourteenth day of the first month, and, owing to the close association of this feast with the events commemorated at Easter, an attempt has been made to follow the ancient system of fixing its date. That this is mainly the result of sentiment is shown by the fact that Christmas and other feasts are kept on fixed days of the solar year; moreover, the coincidence with the ancient method is not perfect, since Easter is tied to one day of the week, which was not the case with the Passover. This fact alone may produce a deviation of six days, so that it is obvious that no serious principle could be involved in increasing the deviation to a fortnight or thereabouts, which is all that a fixed date demands. Many unofficial ecclesiastical pronouncements have shown that there is no strong hostility to such a change. Lord Desborough brought the matter forward in a letter to the *Times* on July 20, and in the House of Lords on the following day, pointing out the inconvenience felt by the schools, universities, law terms, etc., through the variable date. The Earl of Onslow did not give much hope of Government action, but this is clearly a matter for international, not merely national, arrangement. The Astronomical Union in its session at Brussels last July appointed a Committee on Calendar Reform, with Cardinal Mercier as chairman, and it is understood that the date of Easter was one of the subjects of reference. The present time, when so much is in the melting-pot, would seem to be a particularly hopeful one for promoting this and similar reforms.

ASTRONOMY IN TOWN PLANNING.—It is a sign of awakening public interest in astronomy that a paper should be read before the Ottawa centre of the R.A.S. of Canada on the importance of considering practical questions of incidence of sunlight in planning out new towns. The author, Mr. H. L. Seymour, refers to the action of sunlight on bacteria and to the importance of letting all rooms get their share of sunlight, which is best secured by making the corners of the houses point to the four cardinal points, which means that the streets should run from N.E. to S.W. and from N.W. to S.E. He quotes Mr. Horace Bushnell as having put forward the same idea in 1864; but, nevertheless, the tendency has been rather to make the streets run N.-S. and E.-W., with the result that northward walls get no sunshine at all for more than half the year. In the planning of garden cities, where the houses are not contiguous, it is also important to place them so that the shadow of one house may not fall on another, or at least to minimise such incidence. The heights of buildings should also be so regulated that those opposite them are not in perpetual shadow.

The Empire Timber Exhibition.

By ALEXANDER L. HOWARD.

THE Overseas Trade Department of the Board of Trade some time ago conceived the idea of organising an exhibition which should be a representative collection of those timbers which form the forest wealth of the countries which constitute the British Empire. This excellent scheme, possibly the direct outcome of the experiences of the war, was cordially and unanimously supported by the representatives of the Governments overseas.

Among the many lessons learned as a result of the war none was of greater importance than the knowledge that was brought home to us of our great dependence upon the products of the forest for the making and building up of every possible kind of offensive and defensive engine of warfare as well as for the maintenance of the daily requirements of ordinary life. From the time when the proposals of the Board of Trade were first considered every effort was made by the representatives of the different States of the Empire and by the officials at home to see that not a stone was left unturned to show conclusively what it was possible to achieve in the matter of timber production from every source. By a happy chance the date for the exhibition was fixed to coincide with that of the British Empire Forestry Conference, which brought together representatives of the Forest Services throughout the Empire, and there can be no doubt that such an exhibition must form the best possible opportunity for the forest man to gauge the value of the work upon which he is engaged.

The countries of the world may be classed into three grades: one which possesses a competent scientific forest service with practical work in full operation; a second which also possesses such a forest system, but lacks the practical application of theory; and a third which possesses neither scientific nor practical forestry. It is regrettable that until a very recent date the United Kingdom must have been classed in the last category, and, although much has been done in the past few years to remedy the situation, it is doubtful whether the great national importance of the subject has yet been fully realised.

The Empire Timber Exhibition entailed an enormous amount of continuous hard work and persistent energy which eventually resulted in bringing together a collection of many hundreds of timbers from every part of the Empire, and certainly the majority of those of any commercial importance. A collection of this kind is not easy to gather together, and it is doubtful whether such an opportunity is likely to be again available for a very long time.

The following are a few of the more noteworthy of the exhibits of the various countries:

British East Africa.—The considerable forest resources of this country are practically unknown and their exploitation is yet in its infancy. The most important timber is pencil cedar (*Juniperus procera*), which is slightly harder and more brittle than the American variety (*J. virginiana*). So far it has not been much appreciated by British manufacturers, although its importance may be gauged from the fact that in 1910 31,000 logs of this timber were imported into Germany from what was then German East Africa. As the majority of the lead pencils used in this country before the war were of German manufacture, the importance of this supply is obvious.

The Gold Coast.—Supplies of the timbers of the Gold Coast have already been seen in this country, but this exhibit showed many which are unknown here, though, as with other countries, much confusion

arises from the varying vernacular names. The various species of Khaya, the African mahoganies, play the most important part, for this wood, which is generally of fine texture and good quality, has been in very large demand, and extraordinary prices have been realised for it. Another valuable wood is that labelled Odum (*Chlorophora excelsa*), which has also been imported as Iroko, sometimes falsely termed African teak. While it is in itself of great value, and likely to be more so in the future, it possesses none of the qualities of teak with the exception of a superficial resemblance in colour. The wood labelled Kaku, also called Karkoo (*Lophira procera*), is generally known in England as African oak; it possesses unique qualities of strength and durability, and it is to be regretted that supplies seem to be scarce.

Nigeria.—From Nigeria also *Lophira procera* is available, though here it is known as Eki; it is a strong wood, and is reported as being both termite- and teredo-proof. Other heavy constructional woods which resist the white ant and show good promise for the future are Sasswood (*Erythrophloeum guineense*), the gamboge-coloured Opepe (*Sarcocephalus esculentus*), Agboin (*Piptadenia africana*), and Apa (*Afzelia africana*). A particularly fine ebony of large size and beautifully variegated colour is that known as Kawraw (*Diospyros mespiliformis*). First and foremost amongst the woods from this region, however, are the mahoganies, which form the bulk of the supplies. This exhibit was in charge of Mr. Lauchlan.

Western Australia.—The depletion of the forests in the past has reduced the volume of the timber available, but their re-afforestation is now in the charge of Mr. C. E. Lane-Poole, and supplies will probably be assured for the future. One of the chief factors in the great value of the timbers of Western Australia is their durability. Jarrah (*Eucalyptus diversicolor*) and karri (*E. marginata*) sleepers, for instance, 4½ in. by 9½ in., on the Great Western Railway remained sound in the ground for twenty years, and appear to be good for another twenty years, while the trenail has remained in position during the whole period. It should be remembered also that a jarrah or karri sleeper 4½ in. by 9½ in. is better than one 5 in. by 10 in. of any other wood. Jarrah is also shown in the form of flooring, and provides a smooth, hard-wearing surface equal to that of any other hardwood. Telegraph arms in karri were exhibited; these have been extensively used and much appreciated by the G.P.O. for many years. These hardwoods take premier place for such work as piling, wharf-planking, and bridge-building, and, though more costly in their initial outlay than many timbers, prove the most economical ultimately. As a furniture wood jarrah is also excellent; the chairs, tables, and panelling which were exhibited illustrate its value for this purpose.

Canada.—At the Canadian exhibit, which was in charge of Mr. Stokes, were shown two interesting models of wooden houses made of Douglas fir (*Pseudotsuga Douglasii*). Some sixty-nine timbers were shown, of which about twenty-five are of commercial interest, the remainder forming a valuable reserve for future use. Two of the outstanding timbers are the Sitka or silver spruce (*Picea sitchensis*), which might be called the aluminium of timbers, and veneer of basswood (*Tilia americana*), which is used in the making of safety matches. The by-products of the Canadian forests include turpentine, artificial silk and surgical cotton made from sulphide pulp, and the ground-wood pulp which is used in the manufacture of the paper on which the *Daily Mail* is printed.

British Guiana.—The timbers produced from this country, the exhibit of which was in charge of Mr. Herbert Stone, are of very great importance, and provide a source of supply which has never yet been properly realised. With the exception of greenheart (*Nectandra Rodioei*), no import into the United Kingdom worth mentioning has occurred. This fact is evidence of the lack of enterprise which this country displays, because from Dutch Guiana (Surinam) similar woods have been known and appreciated for many years in Holland, France, and Germany. Among the practically unknown timbers which should be in demand are purpleheart (*Copaifera pubiflora*), the rich and brilliant colour of which stands out remarkably even amongst the many brilliantly coloured woods of South America; mora (*Dimorphandra Mora*), a wonderfully durable wood suitable for constructional work and for sleepers; wana (*Nectandra Wana*); brownheart (*Andira inermis*) (this wood, which is called Surinam teak by the Dutch, was named partridge wood by Laslett); locust (*Hymenoea courbaril*); and crabwood (*Carapa guianensis*). All these are fine durable woods suitable for construction in buildings which are required to last for generations.

Indian Empire.—The remarkable exhibit of the timbers of the Indian Empire, both in the raw state and manufactured into furniture and so forth, was the more noteworthy when it is remembered that practically none of these timbers of India had ever before been seen in this country. Even those who were acquainted with the forest wealth of India have not hitherto realised the extent of its commercial value in Europe. Amongst the exhibits were two halls and staircases made respectively in Indian silver greywood and padauk (*Pterocarpus dalbergioides*), a dining-room panelled in gurjun (*Dipterocarpus turbinatus*) and furnished in laurel wood, a drawing-room in sissoo (*Dalbergia Sissoo*), a bedroom in Indian black walnut with panels of walnut burr (*Juglans regia*), and a billiard-room furnished entirely in padauk and panelled in laurel wood. The great possibilities of the Indian timbers were, perhaps, most strikingly shown in the railway coach built by the Great Eastern Railway Co. The constructional portion was entirely of Indian wood, the decoration of the first-class carriage being in Indian silver greywood and that of the third-class in padauk. These presented such an excellent appearance that their increasing use in this direction is certain.

In addition to these larger exhibits were shown chairs, mirrors, and numerous small articles which serve to illustrate the many and varied uses to which the woods may be put. No trouble has been spared to demonstrate the fact that for every purpose for which wood is required the products of the Indian forests can meet the demand. Some two hundred small specimens showed the wide range of colour and texture which is available. Among this large collection of timbers the following are particularly worthy of the most careful attention of those interested in timbers for decorative and constructional work. Gurjun (*Dipterocarpus turbinatus*), a pale brown-coloured wood with a delicate aromatic scent, is an attractive medium for panelling, and one of the best hardwoods for flooring which it is possible to obtain. It is available in large sizes of superlative quality, and at a price which brings it within the range of even the most economical kinds of uses. Padauk is a wood which is unique in its brilliant red to maroon colour. It is exceedingly firm and durable, stands well without shrinking or warping, and is one of the strongest woods it is possible to obtain. During the war immense quantities of padauk were used for saddle-trees and gun-carriages, for which purposes it is difficult to find its equal. It was also used for the felloes of some exceptionally large wheels for heavy guns for use in Russia. The produce of a

species of Canarium, which has been termed Indian white mahogany, is likely to take an important place in the future. It is a smooth, even-grained wood which will be available at a very reasonable price. Haldu (*Adina cordifolia*) is a bright canary-coloured wood notable for the smooth and even regularity of the grain. It is possible to carve it in any direction without splitting—a striking quality which gives it a particular value. Perhaps the finest carving wood which it is possible to obtain, however, is Indian red pear (*Bursera serrata*), which possesses the above qualities in a unique degree. Other woods which are chiefly notable for their decorative qualities are Indian red zebra-wood (*Melanorrhoea usitata*), Indian primavera, yellowheart (*Fagraea fragrans*), and the handsome striped and mottled ebony known as Andaman marblewood (*Diospyros Kurzii*). It becomes abundantly clear that the only thing necessary for these timbers of India to take the important position which their merits deserve is that the representatives of the Government in India should continue to provide regular and certain supplies, and to this end extensive arrangements are now being made.

The United Kingdom.—About seventy varieties of timbers grown in the United Kingdom were shown, and these included such importations as the silver wattle of Australia and the black walnut (*Juglans nigra*) of America. Floorings in yew (*Taxus baccata*), cherry (*Prunus Avium*), and beech (*Fagus sylvatica*), amongst others, illustrated a little-known use for these woods. The decorative effect of English brown oak (*Quercus Robur*) was shown in various articles. Other exhibits, such as the gondola of an aeroplane made in English ash (*Fraxinus excelsior*), called to mind the large part played in the war by the native timbers.

Other countries showing interesting exhibits, of which space forbids mention, were British Honduras, Ceylon, Fiji, Newfoundland, New South Wales, New Zealand, Union of South Africa, Tasmania, and Trinidad.

The Education Act, 1918.

LONDON COUNTY COUNCIL DRAFT SCHEME.

THE Education Act of 1918, which among its provisions requires that draft schemes for giving effect to them shall be submitted by the local education authorities, has resulted in a remarkably interesting document just issued by the Education Committee of the London County Council, in which is set forth not only a scheme for the administration of the Act within the county, but also a most informing summary of the history of education in London during the nineteenth century and of the various legislative enactments passed from time to time, notably those of 1870 and 1902, to increase the facilities and improve the quality of education especially for the large population immediately within its area, now amounting to upwards of 4½ millions. The report further makes clear the present activities of the Committee with its 951 separate elementary schools, in which 695,197 pupils are enrolled, with an average attendance of 590,633, from which figures it would appear that more than 100,000 children are constantly absent. The schools are staffed by 20,000 teachers (less than one-third are men), of whom only 300 are uncertificated. In addition to the ordinary elementary schools there was organised in 1910 a system of central schools to the number of 51, distributed more or less evenly throughout the County of London, and filled with pupils selected partly by means of junior county scholarships at about eleven years of age with a view to an advanced course of training of four years.

The Council, as the local education authority, is concerned not only with the mental well-being of the child, but also with its physical and social welfare. Having regard to the fact stated by Sir George Newman in a recent report, that there were more than one million children in attendance at public elementary schools in England and Wales who were unable by reason of physical or mental defects to take effective advantage of the instruction offered, no feature of the past and future work of the Council can be regarded as of greater importance than the effort to raise and maintain the standard of bodily health and intellectual vigour of the children of London. The statutory medical inspection in the schools is carried out by 57 assistant medical officers and a staff of 208 nurses under the Medical Officer of Health of the county. The county is divided into five areas, each under a divisional medical officer, a superintendent of nurses, a treatment organiser, and a children's work director. During 1919 169,200 cases of various kinds were treated, and for 1920–21 provision is to be made for 40,000 cases more. A fee of 1*s.* is required in each case where the parents can afford it, otherwise the treatment is free.

There is special provision for anæmic and subnormal children, for those with speech defect, of whom there are about 1200 in the schools who need treatment, and for blind and deaf children, of whom there are 317 and 693 of the elementary-school class respectively, whilst there are also 659 partly blind and 117 partly deaf London children.

All these measures denote a seriously important and beneficial advance upon the almost entire neglect of child-life in the nineteenth century. The provision of higher education within the county includes 23 schools provided and maintained by the authority and attended by 8702 pupils, 31 schools with 11,808 pupils aided by the authority, 47 other public secondary schools with 16,462 pupils, 40 schools conducted by religious bodies with 5170 pupils, and, lastly, 421 private schools with 27,295 pupils. The last two groups are regarded as preparatory rather than as secondary. There is thus a total of 562 schools in the county area with 68,807 pupils under instruction, much of which, it is not unreasonable to say in respect of the great majority of the private schools, can scarcely be efficient either in subject or in quality. The Council maintains five training colleges for teachers, one of which is a school of the University of London, and makes maintenance grants to three recognised training colleges within its area for domestic-economy teachers.

The provision of technical education within the county since the passing of the Technical Instruction Acts of 1889 and 1891 comes under review, and is marked by three periods of development. The first covers the years 1889–1904, and embraces the work of the Technical Education Board established in 1893; the second from 1904 to 1909, which followed the traditions and policy of the Board; and the third from 1909 to the present time, which has aimed at a progressive delimitation of the functions of rival institutions and at a general endeavour to co-ordinate all forms of education.

In 1892 a general survey was made of the needs of London as a preliminary to the operations of the Technical Education Board, and, as a result, the Board made direct grants in aid of polytechnics and other institutions for their maintenance and equipment and for the extension of their work. There were 26 technical institutions so aided in 1903, some of which were under the direct control of the Council, and grants were also made to the extent of 33,000*l.* in aid of science and language teaching in the secondary schools. A system of scholarships was

established in aid of boys and girls of ability to obtain an education beyond the primary stages, and to assist adults in their studies in art, science, and technological subjects in day and evening institutions; and the Board, having regard to the importance of educating the future leaders of industry and commerce, not only aided in the establishment of the London School of Economics, but also made grants of 17,000*l*. a year in 1903–4 to institutions and schools of the University of London. This policy has been greatly developed since 1904, when the Council became the local authority for all forms of education. Some measure of the expansion of the work undertaken in the polytechnics may be seen on a comparison of the student-hours worked in the departments of engineering, mathematics, physics, and chemistry in 1900–1 and in 1919 (November), from which it appears that the hours in 1900–1 were 268,344 and in 1919 795,000.

The growth of expenditure in polytechnics, technical institutes, schools of art, science, art, and commercial centres, and in ordinary evening classes is indicated by the following figures:—In 1904 the expenditure was 369,400*l*., and in 1919–20 (estimated) 822,514*l*. Twenty-six special institutions for art, technical, and domestic subjects are now wholly maintained by the Council, and twenty-nine others are aided by annual grants. Twelve polytechnics and colleges receive annual subsidies ranging from 400*l*. to 3500*l*., amounting in the aggregate to 23,250*l*., whilst the block grant made to ten polytechnics and colleges in 1911–12 of 86,381*l*. was increased in 1919–20 to 139,950*l*., exclusive of 60,000*l*. in respect of war bonus and improved salary scales. In 1919–20 an equipment grant was also made to these institutions of 13,900*l*. The Council in 1918 introduced a new scale of salaries for principals and other teachers in technical institutions, whereby the minimum salary for principals in the lowest group was fixed at 440*l*. and the maximum in the highest group at 1250*l*. The salaries for heads of departments range from 440*l*. to 840*l*. (men) and from 340*l*. to 640*l*. (women), and whole-time lecturers' salaries are fixed from 225*l*. to 490*l*. (men) and from 180*l*. to 340*l*. (women). The Council works in close association with the University of London, to which it gives annual grants-in-aid, which at the present time amount to about 47,000*l*. This includes provision for nineteen professorial chairs in languages and literature, mathematics, science, education, and economics. The Council also maintains a school of the University, the London Day Training College, at an annual cost of 10,000*l*., and is spending in 1919–20 about 13,000*l*. in aid of university students, mainly in London, Oxford, and Cambridge, which altogether brings up the annual expenditure in support of university education to about 70,000*l*. Capital grants have further been made at various times in aid of certain schools of the University for the erection and improvement of buildings. Thus grants were made to University College and to Bedford College each of 30,000*l*. Land of the value of 66,700*l*. was also assigned at a peppercorn rent for the new building of the London School of Economics. The grant to the Imperial College of Science and Technology has been increased from 5000*l*. in 1908–9 to 13,000*l*. in 1918–19.

Many of the reforms foreshadowed by the Education Act, 1918, have already been anticipated, such, for example, as the reduction in the size of classes, the establishment of central schools, the promotion of physical training, and the provision of maintenance allowances. The raising of the school age to fourteen *plus* and the reduction aforesaid will necessitate the provision of school-places for 120,000 children, 32,000 of which have been already provided, and will entail the appointment of 200 new teachers each year for ten years. Nineteen per cent., or some 14,000 children between eleven and twelve years of age, are fitted for some special type of school, and the Council has therefore decided to increase the number of central schools already provided from 60 to 100, and to lengthen the course in such schools to five years. Thus some 80 per cent. of the children remain to be dealt with until they reach the limits of the compulsory age, and measures are being taken to ensure the most enlightened treatment of such children in regard to both their physical and intellectual training such as prevails in the secondary schools. The attendance at the secondary schools in London ranges from 1·3 per 1000 in Shoreditch to 18·8 per 1000 in Lewisham. Additional accommodation is urgently needed, and the Council proposes therefore to build four entirely new schools and to rebuild or enlarge seventeen more.

It is anticipated that the new scholarship scheme of the Council and the better conditions of service will attract more candidates to the teaching profession. The report of the Board of Education for 1918 shows that in England only 150 men and 4000 women completed courses of training as teachers, whereas in 1914 the corresponding figures were about 2000 men and 3600 women. The annual requirements of London alone will in the near future be at least 1200, and with the view of meeting in part this demand the Council proposes to build three new training colleges for 750 students, which proposal will involve a capital expenditure of some 600,000*l*. The Council aims ultimately at securing a university course for all teachers. A much enlarged scheme of maintenance scholarships is submitted, the ultimate gross cost of which, including the cost of examinations, is estimated to reach about 1,178,000*l*. in 1931, made up of 730,000*l*. for education and 448,000*l*. for maintenance.

The day accommodation in the present polytechnics, in the various institutes, and in schools for special trades is about 2500, and it is proposed to increase it to 5600. A large amount of original research has been undertaken in the institutions both before and during the war in the domains of chemistry, physics, and engineering, and notably in the industries of photo-engraving, lithography, and tanning. This has led the Council to provide additional facilities to meet the requirements of research. Close consideration has been given to problems arising out of the powers and duties imposed by the Act in respect of adolescents engaged in employment. Provision is to be made next October for about 15,000 young persons, and an equal number will then be added to the total enrolment each succeeding three months for a period of two years. The number will then be 120,000, and in 1928, when those aged from sixteen to eighteen come under the Act, the number will be doubled. Meanwhile, it is proposed to establish as a first provision twenty-two day continuation schools at a cost on capital account of 131,000*l*. and of 116,500*l*. for maintenance. The scheme when fully matured is estimated to cost for the two age-groups 14–15 and 15–16 1,000,000*l*. annually, and when five years later the age-group 16–18 is dealt with the cost may be doubled. The movement of adult education by the W.E.A. has the full sympathy of the Council, which proposes to support it through the University of London.

Pending the re-organisation of the University of London, the system of annual grants, which amount to 46,813*l*. to the University and non-incorporated colleges, will remain as at present. By the Act of 1918 local education authorities may aid any investigation for the advancement of knowledge in or in connection with an educational institution. London, by reason of

the large scale of its operations, offers the most promising field in the world for research in the domain of education, which is the "key" to all original investigation, scientific or industrial, and in connection with the national movement for reconstruction. It includes the study of the mental development of the individuals to be educated and the study of the teaching methods most effective in securing that end. It is therefore proposed to encourage and aid extended educational research. The total estimated expenditure of the Education Committee of the Council for 1920–21 is estimated at 11,711,379*l.*, being for elementary education 9,351,294*l.* and for higher education 2,360,085*l.*, of which sum 5,514,206*l.* is raised from rates, or a rate of 2*s.* 5*d.* in the pound. A forecast is given of the *additional* expenditure in London arising out of the requirements of the Education Act, 1918, which will in 1920–21 amount to 116,000*l.*, and gradually increase until in 1930–31 it is estimated that it will be 3,037,500*l.*, of which sum taxation will bear half the cost, the other half being raised by an additional rate of 8*d.* in the pound on the present assessment. The report extends to 100 pages, and is abundantly illustrated by diagrams, maps, tables, and illustrations of buildings.

The Society of Chemical Industry.

THE Society of Chemical Industry held its thirty-ninth annual general meeting at Newcastle-upon-Tyne on July 13–16, this being the fourth occasion upon which the society has selected Newcastle as its meeting place. Appropriately enough, a series of papers dealing with the manufacture of coke was read and discussed at the first business meeting, whilst the second was devoted to papers dealing mainly with miscellaneous metallurgical questions. Simultaneously the Chemical Engineering Group of the society held a conference devoted to problems connected with filtration and allied methods of separating liquids from solids.

Among the first day's papers two dealt with coke-oven construction. Mr. W. A. Ward discussed "Modern By-product Coke-oven Construction" from the point of view both of the best type to be adopted in different circumstances and of the details of design of the oven itself. Mr. Ward pointed out that the generally accepted view that the regenerative oven is more efficient than the non-regenerative oven is not strictly correct, and that in either case "the surplus energy is the same, because the amount of heat necessary to coke the coal is the same. . . . The difference lies simply in the manner in which the surplus heat is made use of." He showed that it is true that the former type can generally produce a larger amount of power available for use outside the coking plant, but that this is due to the fact that the former uses the more efficient form of power generation, namely, the gas engine as compared with the steam engine. Mr. Ward remarked also that there is no reason why any one of the various types of modern coke-oven should give better results than any other. He proceeded to give much useful information on details of construction; for example, he held strongly with the advantages to be gained in most cases by compressing the coal, but advocated the use of the modern electrically driven top-charging machine instead of the machine making a compressed cake of coal, which is then pushed into the oven, and he gave short descriptions of the modern methods for quenching, screening, and loading the coke.

Mr. W. J. Rees contributed a paper on "The Corrosion of Coke-oven Walls," which he attributed mainly to the sodic chloride and sodic sulphate in the coal, and pointed out that hot, moist air carrying salt vapour has a highly corrosive action on fireclay bricks, much more, in fact, than on other refractory bricks. In the salt glazing of bricks the saline vapour is allowed to come in contact with the brick only at a temperature of about 1200° C., at which the chemical action is rapid; in the coke-oven, on the contrary, the walls of the oven never attain this temperature, with the result that the salt vapour penetrates into the interior of the brick and turns it into a weak, spongy mass, easily broken away. It would appear that the best brick for ovens carbonising salty coal is a good silica brick.

Mr. Harold E. Wright, in his paper "Coke-oven Gas for Town Supply," showed that illuminating gas can be produced more economically in the coke-oven than in the gas retort, and that, wherever circumstances permit of its adoption, the regenerative coke-oven producing metallurgical coke can supply better and cheaper gas to the town consumer than can the ordinary process of gas manufacture.

Dr. E. W. Smith, in "By-products from Coke-oven Gas," dealt with a similar subject from a somewhat different point of view, but came to the same conclusion, stating that it is only necessary to remove sulphuretted hydrogen from coke-oven gas in order to make it suitable for town supply, and that experience at Birmingham has shown that the yields of by-products from coke-ovens were just as good as from horizontal gas retorts.

Messrs. G. W. Henson and S. H. Fowles contributed a paper on "The More Economical Utilisation of the Coke-oven and Blast-furnace Gases for Heating and Power." They added numerous data and calculations to support the view which has been repeatedly put forward within recent years, that with regenerative coke-ovens built near the blast furnaces and steelworks, and with proper cleaning of the blast-furnace gases (for which they apparently prefer the Halberg-Beth method), better results are obtained in iron and steel manufacture and a large surplus of power can be generated by means of gas engines, which can supply all the power required by a modern iron and steel plant, whilst a considerable proportion of the coke-oven gas can be utilised in the melting furnace. They also suggest that a certain proportion of the electricity generated can be applied to the finishing of the steel manufacture in the electric furnace, which they consider has no competitor as an appliance for refining steel.

Amongst the metallurgical papers was one on "Some Properties of 60–40 Brass" by Prof. C. H. Desch. Such brass contains two constituents, the α solid solution containing 70 per cent. of copper and and β solid solution with 53·5 per cent. of copper; this latter constituent is plastic at high temperatures, and enables the metal to be hot-rolled, worked, or extruded. It was found in practice, however, that such brass varied greatly in the ease with which it could be machined, and the present paper deals with the reasons for such variation, which was traced to differences of structure. A fine fibrous structure was found to give the best results, and this can be obtained by using brass containing as nearly as possible 40 per cent. of zinc, extruded at a moderate temperature in very powerful presses.

Mr. D. W. Jones, in a paper on "Chemical Sheet-Lead," showed the importance of using the purest possible lead in connection with acid plant, but that in case of need copper will to some extent counteract the injurious effect of antimony and bismuth.

Mr. D. F. Campbell described "Recent Developments of the Electric Furnace in Great Britain," and showed the progress that had been made in this branch

of metallurgy: "In 1914 the quantity of energy used in electric furnaces in Britain, excluding those used for aluminium, was probably less than 6000 h.p., but on the day of the armistice the total capacity was in excess of 150,000 h.p." The author held that furnaces of more than 25 tons or above 3000-kw. capacity are not advantageous, and that the arc furnace has practically displaced the induction furnace. He pointed out the various existing applications of the electric furnace, and indicated the probable future development of this valuable appliance.

Dr. E. F. Armstrong read a paper on "Catalytic Chemical Reactions and the Law of Mass Action," in which he reviewed the present state of our knowledge of catalytic reactions, particularly as applied to the hydrogenation of certain oils. He held that the curve of catalytic action is linear and not logarithmic, and that the latter curve has been obtained by a number of observers owing to the fact that they had been working on substances in which some poison formed part of the substance to be hydrogenated, which destroyed the catalysts and thus gave the curve a logarithmic form. He further claimed that catalytic action is not a purely physical phenomenon, but is due to the formation of loose additive chemical compounds, of the existence of which he produced some evidence.

At the conference of the Chemical Engineering Group the theory of filtration was discussed in two papers, "The Principles of Technical Filtration," by Dr. E. Hatschek, and "The Design of Mechanical Filters," by Mr. Balfour Bramwell, whilst the filtration of gases was dealt with by Mr. J. M. Brown. Mr. E. A. Alliott contributed a paper on "Recessed Plate and Plate-and-Frame Types of Filter Press: Their Construction and Use," in which he compared the two types and the details of their construction; he also discussed various methods of feeding, the selection of filter-cloths, and other important points in the use of filter presses, and gave data as to the results obtained in certain typical examples.

Three papers dealt with centrifugal machines, namely, "The Sturgeon Automatic Self-Discharging Centrifuge for Separating Solids from Liquids," by Mr. R. A. Sturgeon; "The Sharples Super-Centrifuge," by Mr. S. H. Menzies; and "A New Process for Centrifugal Filtration," by Mr. W. J. Gee. The last-named appliance differs from most centrifugal machines in that it makes use of a filtering screen, so that it does really perform a process of filtration. Dr. W. R. Ormandy in his paper, "The Filtration of Colloids," showed the effect of electro-osmotic action on colloids and suspensoids, and illustrated these by a series of experiments with a suspension of clay.

Imperial Cancer Research Fund.

THE eighteenth annual meeting of the Imperial Cancer Research Fund was held on July 22, the Duke of Bedford presiding. Sir William Church, in moving the adoption of the report, gave a summary of the investigations during the past year; in this he stated that the Director had continued the autologous grafting experiments, in which by transplanting an animal's own tumour to a part of its body away from the site of the primary growth an artificial secondary growth is established. The formation of secondary growths is the most certain evidence of the cancerous nature of a growth. It is to be hoped, therefore, that this method will be more widely applied as a control in the experiments on the production of cancer by chronic irritants which are being undertaken in so many laboratories throughout the world. In these experiments the most definite proof of malignancy is essential to progress.

Dr. Cramer has examined the action of a number of inorganic substances on cancer cells. The first step in these investigations is to expose emulsions of a transplantable tumour to the reagent in the test-tube and find out by inoculating the treated emulsion into susceptible animals the amount of damage produced. Salts of cerium were found to be the most active of those tested. Manganese and uranium salts were less potent, and the other elements experimented with were without effect in strengths which could be tolerated by the experimental animals. None of these substances, however, had any influence on growing tumours—a failure probably due to the irregularity of the circulation in the tumours, which delays the access of the reagents to the cells, coupled with their rapid elimination by the kidneys and bowels. This is one of the difficulties constantly met with in direct therapeutic experiments on cancer. The cancer cell is so like the normal cells of the body that agencies which destroy it are also dangerous to life.

Before we can plan a rational method of treatment it will be necessary to know more of the vital processes in cancer cells and the nature of the very delicate differences between them and the normal. A beginning has been made with the study of cell-respiration. Respiration is essentially a combustion process, oxygen being taken in and carbon dioxide given off. These are only the first and last terms, however, of a series of chemical equations, so that there is room for great variety in the intermediate stages, even if the final result should be the same.

Dr. Drew has approached the problem by studying the rate of decolorisation of dilute methylene-blue solution by normal and cancer cells. With this method there is a wide difference between the two, decolorisation being much more rapid with normal cells. Dr. Russell and Dr. Gye have suspended the tissue emulsions in fully oxygenated defibrinated blood and measured the rate at which oxygen is abstracted on incubation at body-temperature. By this second method the differences are much less pronounced, and it is found that the more rapidly growing tumours, with significant exceptions, absorb more oxygen than those which grow slowly. The investigations are being continued, and give promise of interesting light on this fundamental feature of the life of cancer cells.

The Duke of Bedford, in moving a vote of thanks to the executive committee and to others who have assisted in the work of the Fund during the past year, referred to the wide range of investigation, covering such important researches as those relating to (1) experimental induction of cancer; (2) respiration in normal tissues, which is a fresh line of research in connection with cancer; and (3) experiments on the action of chemical substances on cancer cells in the test-tube and in the body; and to the very technical investigation of the Director on grafting; and noticed with satisfaction that the Fund is again in a position to assist investigators at home and abroad with tumour material for experimental purposes.

Liverpool School of Tropical Medicine.

THE Sir Alfred Jones Laboratories of the Liverpool School of Tropical Medicine were formally opened by Lord Leverhulme on Saturday, July 24, Sir Francis Danson, chairman of the School, presiding. Prof. J. W. W. Stephens announced the award of the Mary Kingsley medal to the following distinguished scientific workers:

DR. A. G. BAGSHAWE, C.M.G., well known for his researches on sleeping sickness in Uganda. Since 1908 Dr. Bagshawe has been director of the Tropical Diseases Bureau and general editor of the Tropical Diseases Bulletin. This publication occupies a unique

position in the world; it is of the utmost value to all workers in tropical medicine, and its success is due to the tireless devotion of its editor.

DR. ANDREW BALFOUR, C.B., C.M.G., director-in-chief of the Wellcome Bureau of Scientific Research, London. Dr. Balfour was director of the Wellcome Tropical Research Laboratories, Khartum, from 1902–13. His knowledge of the theory and practice of tropical sanitation is unsurpassed. His intellectual activities also overflow into literary channels, and he known as the author of novels and tales of adventure.

PROF. R. T. LEIPER, helminthologist to the London School of Tropical Medicine since 1905. Prof. Leiper has established a world-wide reputation for his knowledge of those parasitic worms that affect man, more especially in tropical lands. His recent elucidation of the part played by fresh-water snails in the transmission of the Bilharzia disease of Egypt is of the greatest scientific and economic importance.

MAJOR E. E. AUSTIN, D.S.O., assistant in the British Museum (Natural History). Author of numerous monographs on flies. Especially well known to students of tropical medicine for his monograph on the tsetse-flies.

DR. A. L. GUILLAUME BRODEN, director of the State School of Tropical Medicine, Brussels. Formerly director of the Bacteriological Laboratory at Leopoldville, Belgian Congo. Has published numerous works on trypanosome diseases of man and domestic stock.

MRS. ALBERT CHALMERS, in recognition of the work of the late DR. A. J. CHALMERS, who succeeded Dr. Balfour as director of the Wellcome Tropical Research Laboratories, Khartum. Dr. Chalmers was joint author with Dr. Castellani of a most comprehensive text-book of tropical medicine.

PROF. B. GRASSI, professor of comparative anatomy, University of Rome. Distinguished as a zoologist. Played a leading part in Italy in demonstrating the transmission of malaria by Anopheline mosquitoes.

DR. F. MESNIL, professor at the Institut Pasteur, Paris. Joint author with Prof. Laveran of the standard work on trypanosomiasis.

DR. EDMOND SERGENT, director of the Institut Pasteur, Algeria. Dr. Sergent is the elder of two brothers greatly distinguished for their researches in tropical medicine.

DR. C. W. STILES, professor of zoology, United States Public Health and Marine Hospital Service; scientific secretary of the Rockefeller Sanitary Commission for the Eradication of Hookworm Disease—a disease which was responsible for widespread mental and physical deterioration in the Southern States of America.

DR. T. ZAMMIT, who made a fundamental observation which led to the discovery that goat's milk was the source from which man contracted undulant fever. His archæological researches on the megalithic remains of Malta are well known, and the University of Oxford has recently shown its appreciation of his work by conferring on him an honorary degree.

After the ceremony the laboratories were inspected by the large, distinguished gathering of scientific and influential people, and general admiration was expressed for the completeness of the building and its equipment. The well-furnished library and the museum, which already contains many interesting exhibits, attracted considerable notice, while the lighting and spaciousness of the main laboratory were also much commended.

The occasion was marked by the issue of an interesting illustrated "Historical Record," tracing the progress of the School from its foundation in 1898 to the present time.

At a banquet held in the evening Sir Francis Danson appealed for a sum of 100,000*l.* to meet the increased cost of maintenance of the Liverpool Laboratories and of the new Sir Alfred Jones Tropical Laboratory, now in course of erection at Sierra Leone. Sir Francis Danson himself contributed to the fund a sum of 1000*l.*, in memory of his son who fell in the war.

Central Headquarters for British Chemists.

AT a dinner held in honour of Lord Moulton on July 21, Sir William Pope announced that a public appeal was about to be made for funds for the erection of central headquarters for British chemistry. None of the chemical bodies has the accommodation for a meeting of more than two hundred persons, or adequate library space. The Chemical Society conducts its business at Burlington House, Piccadilly, in rooms provided by the Government nearly fifty years ago, when the membership was about one-fifth of what it is to-day. The Institute of Chemistry possesses a good building in Russell Square, completed during the first year of the war, but it is barely adequate for the present activities of the institute, which has to look to colleges for hospitality for any general meeting of unusual interest and for lectures. The Society of Chemical Industry and the Society of Public Analysts hold their meetings at the Chemical Society's rooms. Neither of these bodies nor any other which is concerned with chemistry, such as the British Association of Chemical Manufacturers, the Faraday Society, the Biochemical Society, and those devoted to the various branches of technology—brewing, dyes, glass, ceramics, iron and steel, non-ferrous metals, leather, concrete, petroleum, and so forth—possesses accommodation to compare with the spacious halls and headquarters of the Institutions of the Civil, the Mechanical, and the Electrical Engineers, and of the Royal Society of Medicine.

The appeal, which will be made by the Federal Council for Pure and Applied Chemistry, on which practically all the chemical interests of the country are represented, has the cordial support of Lord Moulton, who, as Director-General of Explosives Supplies, Ministry of Munitions, repeatedly acknowledged the services rendered during the war by these scientific, technical, and industrial bodies.

The scheme, which aims at providing under one roof, so far as is practicable, a common meeting-place, library, and editorial facilities for technical journals, is highly desirable, and indeed imperative, as a matter of supreme importance to the welfare of the whole country in relation to questions of defence and the maintenance and development of all branches of industry and commerce which depend on the applications of chemistry. The sum required for building is estimated at 250,000*l.*; a similar sum is required for establishing a chemical library and to provide for the compilation and production of works of reference in the English language.

University and Educational Intelligence.

LEEDS.—Owing to the unavoidable growth of the expenditure necessary for the maintenance of the efficiency of its work, the council has come to the conclusion that an increase must be made in the scale of fees charged to students for tuition and examination. The increase has been kept as low as possible, in no case being more than about 17½ per cent.

The council has instituted an Appointments Board for the purpose of supplying students at the end of their University career with information about vacant appointments. Mr. W. R. Grist has been appointed the first secretary of the board.

Mr. G. C. Steward has been appointed assistant lecturer in applied mathematics.

LONDON.—Mr. V. H. Mottram has been appointed as from September 1, 1920, to the University chair of physiology tenable at King's College for Women Household and Social Science Department. He is at the present time head of the Animal Nutrition Laboratory at Messrs. Lever Bros.

Dr. W. S. Lazarus-Barlow has been appointed to the University chair of experimental pathology at Middlesex Hospital Medical School. Since 1903 he has been director of the Cancer Research Laboratories at Middlesex Hospital.

Dr. J. C. Drummond, lecturer in physiological chemistry at University College, has been appointed as from September 1, 1920, to the University readership in that subject.

The following doctorates have been conferred by the Senate:—*D.Sc. in Botany:* Miss Kate Barratt, an internal student of the Imperial College, Royal College of Science, for a thesis entitled "A Contribution to our Knowledge of the Vascular System of the Genus Equisetum." *D.Sc. in Chemistry:* Mr. E. E. Turner, an internal student of East London and Goldsmiths' Colleges, for work carried out for British Dyes, Ltd., and the Ministry of Munitions. *D.Sc. in Experimental Psychology:* Mr. G. E. Phillips, an internal student of University College, for a thesis entitled "Mental Fatigue." *D.Sc. in Mathematics:* Mr. G. B. Jeffery, an internal student of University College, for a portion of a thesis: Part ii., "The Motion of a Viscous Fluid," and part iii., "Whittaker's Solution of Laplace's Equation." *D.Sc. in Physics:* Mr. G. D. West, an internal student of East London College, for a thesis entitled "The Forces Exerted on Surfaces Exposed to Radiation." *D.Sc. in Zoology:* Mr. F. J. Wyeth, an internal student of King's College, for a thesis entitled "On the Development of the Auditory Apparatus in *Sphenodon punctatus.*"

At the last meeting of the Senate of the University the question of the acceptance of the Government's offer to provide a site at Bloomsbury was again under discussion. A letter was considered from the President of the Board of Education stating that the Government was prepared to continue to be responsible for maintenance, rates, etc., in respect of the new University headquarters buildings, and also, when the time comes for King's College to vacate the existing premises in the Strand, to ask Parliament for authority to purchase the buildings at a fair valuation. The Senate was, however, unable to make a similar offer in respect of the building at present occupied by the University at South Kensington, which (unlike the King's College building) was not erected from funds raised by the University. Eventually the Senate resolved:—"That, while recognising and welcoming the desire of the Government to assist the University, the Senate, in view of the important issues involved and the uncertainty as to the nature of the offer in many respects, desire time for further consideration and consultation with the Government; and that the Government be requested to keep their offer open to allow time for such further consideration."

The following appointments have been made at King's College:—Dr. J. A. Hewitt, lecturer and demonstrator in physiology; Dr. O. Inchley, lecturer in pharmacology; Mr. J. E. Hadfield, lecturer in psychology; Mr. C. S. Salmon, lecturer in physical chemistry; Mr. H. W. Cremer, lecturer in inorganic chemistry; Mr. W. Partridge, lecturer in chemistry (Public Health); Mr. H. T. Flint, lecturer in physics; Miss C. W. M. Sheriff, assistant lecturer in mathematics; and Mr. L. D. Stamp, demonstrator in geology.

MR. J. HIGHAM, senior physics master at the Durham Johnston School, has been appointed lecturer in physics and electrical engineering in the University of Manchester.

MR. E. RAWSON, head of the engineering department of the Portsmouth Municipal College, has been appointed principal of the Municipal Technical Institute, West Bromwich.

MR. S. MANGHAM, lecturer in botany at Armstrong College, Newcastle-upon-Tyne, has been appointed to the chair of botany at the University College of Southampton.

IN Pamphlet No. 8 just issued by the Bureau of Education, India, Mr. L. T. Watkins deals with "Libraries in Indian High Schools." The pamphlet gives a useful list of selected books, and provides excellent suggestions as to the principles which should govern the choice and classification of volumes for school libraries. Its usefulness should not be limited to India; librarians of schools in the United Kingdom and in other parts of the Empire would find it well worth reading. The pamphlet is published by the Superintendent, Government Printing, Calcutta, and the price is four annas.

THE address of Sir E. Sharpey Schafer, of Edinburgh University, on "The University Problem," delivered at Cardiff in January last, and now issued in pamphlet form, deals with a question of grave importance to the educational, and therefore to the social, productive, and political well-being of the nation. Sir Sharpey Schafer pleads for a wider outlook and a clearer vision of the needs of higher education of the university type. He deprecates the idea that universities must find their location in large cities, and pleads for the open air and the countryside as involving far less expense in both sites and buildings, which latter he would plan so as to be of not more than one or two stories in height. In support of his contention he cites the cases of London and Edinburgh, to which may be added those of other cities in the North of England. The ideal environment for a university, he claims, is an academia, a place for undisturbed work whence the sights and sounds of the city are excluded. He alludes to the campus surrounding many an American university, extending from a hundred acres to space to be reckoned in square miles, which often constitutes one of the most beautiful features of the city in which it is situate. Why should not London with its seven million residents have as many university centres as Scotland, Sweden, Ireland, or Yorkshire with far smaller populations? The universities ought to find their financial support in the State, since the education they give is essential to its welfare and an asset of first-rate value. There should be no restriction to the entrance of the genuine, well-qualified student, no matter whence he comes. Original research should be fostered, and only teachers capable of it appointed. The pursuit of new knowledge is essential. The arguments set forth in furtherance of the claims of university teachers and the statements adduced in their support are worthy of serious attention at the present critical time.

Societies and Academies.

PARIS.

Academy of Sciences, July 12.—M. Henri Deslandres in the chair.—L. **Maquenne** and E. **Demoussy**: The catalytic action of copper salts on the oxidation by air of ferrous compounds. Copper salts accelerate the oxidation of ferrous salts by air, even in dilutions so great as 0·2 mgr. of copper per 100 c.c. of solution. The amount of oxidation depends on the nature of the acid present, and is in direct relation with the degree of hydrolytic dissociation.—P. A. **Dangeard**: Vacuome, plastidome, and spherome in *Asparagus verticillatus*.—F. **Widal**, P. **Abrami**, and M. N. **Iancovesco**: The possibility of promoting the hæmoclasic crisis by the intravenous injection of portal blood collected during the digestive period. The action of the liver on the proteids of incomplete disintegration arising from digestion and carried by the portal vein. An experimental proof that the gastro-intestinal mucous membrane absorbs not only amino-acids, but also compounds in which the proteolysis is incomplete. These products are present in the portal vein for about two hours and a half after a meal, and their injurious action upon the general circulation is prevented by the liver.—H. **de Chardonnet**: The influence of the American rocking-chair upon the respiration.—J. A. L. **Waddell**: The economical use of special alloy steels in the construction of bridges. The higher elastic limit of a special steel compared with that of an ordinary carbon steel may more than compensate for the increased price. Some detailed examples are given.—C. E. **Guillaume**: The anomaly of elasticity of the nickel steels: The realisation of an elinvar and its application to chronometry. The limitations of nickel steel watch-springs are discussed, and a new ternary nickel-chromium steel alloy suggested, containing chromium with small quantities of manganese, tungsten, and carbon equivalent to 12 per cent. of chromium. The results with springs of this material used with a balance-wheel made of a single metal have proved extremely satisfactory. The change of temperature from 0° C. to 30° C. with a watch fitted with one of these springs was two seconds in twenty-four hours, and the rate was practically a linear function of the temperature.—G. **Fubini**: Projectively applicable surfaces.—L. E. J. **Brouwer**: Enumeration of the classes of representations of a surface on another surface.—M. **Galbrun**: The application of the equations of elasticity to the deformations of a helical spring.—P. **Chevenard**: Study of the elasticity of torsion of nickel steels with a high proportion of chromium. A study of three series of ferro-nickels containing approximately 5, 10, and 15 per cent. of chromium. The results are given graphically in three diagrams.—E. **Jouguet**: Remarks on the laws of resistance of fluids.—G. **Sagnac**: The two simultaneous mechanics and their real connections.—M. **Pauthenier**: Study of the ratio of the absolute retardations in carbon bisulphide for increasing durations of charge. The appearance of electro-striction. When the duration of the charge of the Kerr condenser much exceeds a millionth of a second, the ratio of the retardations in carbon bisulphide is no longer equal to −2. The contraction of the liquid under the influence of the electric field, electro-striction, complicates the results; when the time of change is $8{\cdot}1\times10^{-8}$ seconds, the effect of electro-striction exactly compensates the double refraction for the vibrations perpendicular to the field.—C. **Florisson**: The galena-metal contact rectifier. Artificial increase of sensitiveness.—H. **Weiss**: The constituents formed by reciprocal penetration of zinc and copper at a temperature where one of the two metals and all their alloys are in the solid state. The constant temperature required for these experiments was secured by the use of a sulphur vapour bath under a reduced pressure, the temperature thus obtained varying only at most 1° from 410° C. Micrographic methods were used for studying the resulting alloys, and two photographs illustrating the results are reproduced.—MM. **Lespieau** and **Garreau**: The phenylpropines. The reaction between benzyl chloride and the monosodium derivative of acetylene failed to give benzylacetylene, the isomer phenylmethylacetylene being the only product. The same substance was obtained by starting with epidibromohydrin and phenylmagnesium bromide and treating the resulting compound, $C_6H_5{\cdot}CH_2{\cdot}CBr{:}CH_2$, with alcoholic potash. A yield of 40 per cent. of the desired benzylacetylene was obtained by the interaction of phenylmagnesium bromide and propylene tribromide.—G. **Mignonac**: The catalytic hydrogenation of nitriles: mechanism of the formation of secondary and tertiary amines. The best explanation of the secondary reduction products arising from the reduction of benzonitrile by hydrogen in presence of nickel and working in an anhydrous liquid is that the primary reduction product is benzaldimine, $C_6H_5{\cdot}CH{:}NH$. This can give benzylamine by direct reduction and benzalbenzylamine by condensation, and the latter compound has been isolated in quantity.—G. **Zeil**: The proportional constant relating seismic frequency with rainfall.—R. **Abrard**: The geological constitution of Djebel Tselfat, Western Morocco.—G. **Arnaud**: A bacterial disease of ivy, *Hedera helix*.—C. **Porcher**: Milk and apthous fever. Comparisons of the quantity and quality of the milk from apthous teats of a cow when the milk is retained and drawn off.—A. **Vandel**: Reproduction of the Planaria and the meaning of impregnation in these animals.—M. **de Laroquette**: Analogies and differences of biological action of the various parts of the solar spectrum.—C. **Pérez**: A new Cryptoniscian, *Enthylacus trivinctus*, an intrapalleal parasite of a Sacculina. A case of parasitism of the third degree.—J. **Dragoiu** and M. **Fauré-Fremiet**: Histogenesis and time of appearance of different pulmonary tissues in the sheep.—G. **Bertrand** and Mme. **Rosenblatt**: Does chloropicrin act upon soluble ferments? From experiments carried out with sucrase (from yeast and from *Aspergillus niger*), amygdalinase, urease, catalase, zymase, laccase, and tyrosinase, it was found that chloropicrin exerts only a feeble inhibiting action on soluble ferments, and some other explanation must be found for its highly toxic action upon living cells.

CAPE TOWN.

Royal Society of South Africa, June 16.—Dr. A. Ogg, vice-president, in the chair.—L. **Péringuey**: Note on a recent discovery of stone implements of Palæolithic type throwing light on the method of manufacture in South Africa. The author described a collection of Palæolithic stone implements from the Montagu Caves, and showed that the completed implement is flattened, rounded at one end and tapering to a point at the other, and being chipped to a sharp edge all the way round. From this demonstration it is now possible to pronounce that many of the implements so far known which are blunt at one part or another are unfinished or damaged specimens. Further, it is shown that a large block was chipped down in order to form a relatively small delicately worked implement, and the very large chipped stones that have sometimes been found are seen to be initial stages in the manufacture.—W. A. **Jolly**: The reflex times in *Xenopus laevis*. The author described his method of measuring exactly the reflex times in the reflexes from the limbs of the South African clawed frog or toad,

and gave a note of the times ascertained in the decerebrate animal.—C. L. **Herman**: Notes on the Platana of the Cape Peninsula. The marked difference in the shoulder-girdle of the Platana of the Cape Peninsula from that described and figured by Boulenger as appertaining to *Xenopus laevis* was pointed out. The importance of the shoulder-girdle as a basis for systematic classification was referred to, and the probability of this Platana being a primitive form was suggested. The formation of the external nasals was described, and attention directed to the horny epidermal fold on the superior half of the nasals which gives it rigidity. The synchronous contractions of the nasals and the movement of the premaxilla and maxilla were described and their nature was discussed. It was suggested that this occurs in all the Xenopus, and the wish was expressed that this remarkable phenomenon, now described for the first time, should be looked for in the case of water-frogs generally.—J. R. **Sutton**: A possible lunar influence upon the velocity of the wind at Kimberley (second paper). In this paper the author continues the investigation described in a previous paper under the same title. A table and a diagram are given showing the deviations of wind-speed at the times of perigee from the monthly means, arranged in hours of the lunar day. The ranges of velocity deduced are somewhat greater than those previously found for the average of all lunar distances. The noon and midnight perigee curves are remarkable, and suggest that the wind-speed deviations attributable to the moon are largely due to the superimposition of the lunar air-tide upon the diurnal variations of wind velocity. Thus no two different places could be expected to have quite the same velocity deviation curves.

University Grants.

A FEW weeks ago (June 17, p. 477) reference was made in these columns to the financial position of the Universities and institutions of University rank, and a plea was put forward for more adequate Government financial support. We are not unmindful that the Government has already recognised that it has responsibilities in this respect, but we greatly doubt whether it has fully realised their extent. The majority of these institutions are of comparatively recent foundation, and from the first have led a precarious existence; restricted resources and even poverty have almost uniformly been their lot. Nevertheless, they have ministered to the needs of higher education in a truly remarkable way; they have helped this country to hold its own in the face of world competition, and materially contributed to its success in the Great War. This being so, one would think that the encouragement and development of higher education would be among the first and primary cares of the Government. While we believe that this really is the intention, yet, if we may judge from certain proposals recently made, the Government does not fully appreciate the present state of affairs in the Universities. Apart from the question of new and additional accommodation due to the great influx of students, and altogether apart from the necessities of internal development which are yearly becoming more and more insistent, there stand out the dominant facts that the great body of University teachers are quite inadequately remunerated, and that there are no really practicable sources which can be tapped to provide proper and adequate emoluments for them. It is within our knowledge that the present economic position is pressing most severely upon a large number of University teachers, and that the financial position of many Universities is precarious.

If there is one thing more than another which has been insistently pressed upon the University Grants Committee on its visitations—and, we are glad to say, has uniformly received a sympathetic hearing—it is this question of inadequate remuneration. A University is essentially a corporation of men and women, and if the teaching side of this corporation is dissatisfied or labours under a sense of injustice, its work loses its spontaneity and efficiency, and the interests of higher education, and with them those of the nation, will suffer in consequence. Obviously this is a truism which need not be laboured. When men and women have to eke out inadequate stipends by extraneous work the effects, though almost imperceptible at first, are bound to be serious in the long run. But this is not all. Inadequate remuneration reacts unfavourably upon the supply of efficient teachers. Talented young students will look elsewhere for their life's work. Already, as we have indicated on a previous occasion, the financial inducements of industry have depleted the Universities of some of their ablest teachers, and there are no uncertain indications that this depletion is likely to become more serious still.

Now, the Chancellor of the Exchequer recognises that the Government must do more, and he proposes to ask Parliament to increase the Treasury grant-in-aid from 1,000,000*l.* to 1,500,000*l.* in the Estimates for 1921–22. He does not propose to ask for any supplementary grant this year. We respectfully submit that this proposal is totally inadequate. As a matter of fact, we would point out that Parliament is not to be asked for a larger sum than is given this year; what is proposed is simply to make the non-recurrent 500,000*l.* recurrent. We repeat that such a sum is totally inadequate for present needs. A recent statistical inquiry instituted by the Association of University Teachers has elicited the fact that the average salary at present paid to an assistant lecturer is 250*l.*; to a lecturer, 366*l.*; and to a professor, 800*l.*, from which, of course, must be deducted the superannuation premiums of 5 per cent. or so. When we consider the largely increased salaries paid to teachers in other branches of the profession, let alone the inducements offered in industry, it is obvious that such average salaries will not attract the right type of teacher to the University in the future. We repeat that the proposed grant-in-aid is absolutely inadequate under present economic conditions, and would respectfully urge upon the Chancellor of the Exchequer to reconsider the whole question.

If this is the case regarding the general financial

position, what must be said about the question of superannuation? A short time ago a deputation consisting of representatives of the governing bodies of the Universities and institutions of University rank in England and Wales, together with representatives of the Association of University Teachers, waited upon the Chancellor of the Exchequer to put before him certain proposals regarding the present unsatisfactory state of superannuation in the Universities. Briefly these proposals were to the effect that the Government should grant University teachers the same, or similar, superannuation benefits as already granted to other branches of the profession under the School Teachers (Superannuation) Act, 1918, *plus* certain other benefits which the University teachers were prepared to pay for themselves by an annual premium on their salaries. The deputation was a most representative one and absolutely unanimous in its proposals. We now understand that the Chancellor is "prepared to consider the advisability of proposing to Parliament a further non-recurrent sum to assist the Universities in meeting the grievance of those senior members who are precluded from profiting to the full by the benefits of the University Superannuation Scheme." At the same time, it is announced that the Council of the Federated Superannuation System of the Universities has undertaken to obtain the information upon which the proposed non-recurrent grant will be made.

In all this there is not a word about giving University teachers the same, or similar, privileges that school teachers have in their non-contributory Government scheme. Not a word about facilitating the transference of teachers from the schools to the Universities or from the Universities to the schools, so that there would be no loss of superannuation benefits on the transference. Not a word about full retrospective benefits, irrespective of whether the service has been in schools or in Universities. Not a word about the consequent unity of the teaching profession. It would seem that the policy is to make such transference as difficult as possible. Now, obviously such a policy cannot be in the interests of education. It may be that we have placed too narrow an interpretation upon the words quoted above. We hope so. For, unless we are profoundly mistaken, the great bulk of the University teachers will be bitterly disappointed if the Government does not at least grant them benefits equivalent to those already granted to 95 per cent. of the teaching profession in the country.

Tanks and Scientific Warfare.

Tanks in the Great War, 1914–1918. By Brevet-Col. J. F. C. Fuller. Pp. xxiv + 3[illegible] + vii plates. (London: John Murray, 1920.) Price 21*s*. net.

THIS remarkable book is a clear and straightforward history of how the British Army learnt to use the most revolutionary weapon the great war produced. It is written by a confirmed believer in that weapon, whose belief probably became more and more complete as the Tank Corps gradually grasped a few of the principles involved in its use. It is somewhat of a pity that the author does not devote a chapter to the process by which the Tank Corps arrived at the tactics which eventually proved so successful. It took something like two years to overcome the prejudices raised against tanks in official quarters, and this in war-time, when progress is relatively rapid compared with that in peace. It is therefore to be hoped that the principles so ably set forth by Col. Fuller, and so well proved in the late war, will never again be overlooked.

It is only natural that it took many months for the Tank Corps to evolve anything like effective tank tactics. Many methods had to be tested in battle before being discarded, and it is not unusual, but rather a matter for congratulation, if the tactics evolved for the battle of Hamel were primarily suggested by the Australians, for it serves to show the close co-operation obtained, and the openmindedness of those in the Tank Corps to adopt the suggestions of others.

The history of tank tactics is an instance of how an effective weapon may be entirely wasted unless its use is understood. As to how much blame attaches to the Tank Corps for the use of tanks in the Ypres salient and similar misuses up to the first battle of Cambrai the author is silent, nor does it matter much, except that it serves to show how necessary it is for the expert on the new weapon to have some say in such matters. However, if, as Col. Fuller says on p. 58, the following lessons were learnt as the result of the first use of tanks on the Somme in 1916, especially No. 2, then the later tank actions need a lot of explanation.

The battle of Cambrai, although it demonstrated what tanks in numbers over good ground and without a preliminary bombardment could do, yet would have been a far greater success had the tank tactics as finally adopted at the battle of Hamel been in use. There is no question that the town of Cambrai itself would have been taken on the first day of the attack had proper cooperation with the infantry been maintained. The

hold-up of tanks at Flesquières (p. 149) would not have taken place had the infantry been following the tanks closely, and could also have been got over by the tank crews getting out of their machines and stalking the field-gunner as infantry. The infantry on this occasion were several hundred yards behind!

This book makes one hope that someone will write the history of tanks from the civilian point of view. Read in conjunction with this excellent work, some of the more obvious mistakes in the past might thus be avoided in the future. It is now common knowledge that neither the War Office nor G.H.Q. welcomed "tanks," although it might be inferred from this book that they did so. The tank was fathered by the Navy, and had reached success before it was handed over. Its history was briefly as follows, and it is illuminating how little the Army contributed.

In Mr. Winston Churchill's letter to the Prime Minister of January, 1915, he remarks: "It is extraordinary that the Army in the field and the War Office should have allowed nearly three months of warfare to progress without addressing their minds to its special problems." It *was* extraordinary, and more so when they turned down any proposals made to them for breaking down the "trench warfare" into which both armies had settled. Mr. Winston Churchill made direct reference in this letter to armoured caterpillars and the way in which they should be employed.

There were many schemes put forward for carrying out this suggestion, but the successful one was produced by Major W. G. Wilson, who was then a lieutenant, R.N.V.R., in the Royal Naval Armoured Cars. Working in conjunction with Mr. (now Sir) William Tritton at the works of Messrs. Foster, of Lincoln, the machine was constructed and afterwards demonstrated at Hatfield. The designers called for a statement from the Army as to the width of trench to be crossed, height of parapet to be climbed, etc., and this was drawn up by Col. Swinton, who stands out at this time as practically the only champion tanks had in the Army.

Although the Navy fathered the production of the first tank, it was equally fortunate that after its success had been demonstrated at Hatfield to representatives from the War Office and G.H.Q., France, the future of tanks was entrusted to Sir Albert Stern. It was he who, when the first order for tanks was cancelled by the War Office, refused to cancel the order, and said he would, if necessary, pay for them himself.

Again, fate was kind to them on their first venture at the battle of the Somme. On September 15, 1916, two companies, each consisting of twenty-eight tanks, went into action. The company commanded by Major Summers got twenty-two machines into action, but only two of the other company crossed into No-man's Land. It is more than likely that, but for the efforts of Summers and his technical officer, Knothe, tanks would have been voted a failure and never given another trial. It is worth noting that both these officers were, prior to the war, civilians

Again, it seems never to have been pointed out how the Army authorities failed to grasp the full importance of other proposals of the tank tribe. In 1916 the need of the moment was such protection against the machine-gun, but the early pioneers of the tank movement saw far greater possibilities in the caterpillar track. It was evident that roads and railways were the serious limiting factors to our armies. All supplies had to go by rail and road, and as these could be destroyed by the enemy's long-range artillery, the obvious need was for an alternative—something that could do without road or rails, and cross ploughed fields, shelled areas, hedges, and small rivers. The caterpillar track as used on tanks had been proved to be capable of doing this. Rightly or wrongly, the first attempt was made to design a caterpillar gun-carriage that would take a 5-in. gun or a 6-in. howitzer, or alternatively could be used to carry a large number of rounds of ammunition for either of these guns. It was designed so that the gun could be trained and fired from this movable platform, and the whole be capable of crossing shell-holes and trenches like the tank. The machine was tested at Shoeburyness, the gun being fired and trained with ease. Its value was never realised, and the scheme was allowed to drop. True, fifty machines of the first type were built, but nothing was ever made of the generic idea, and a second improved type, in which the faults of the first had been overcome, was allowed to lapse.

In the autumn of 1918 the value of a cross-country tractor was realised to the extent that many thousands were ordered here and in the U.S.A., but again "realisation" came too late, and none materialised.

As already stated, the Tank Corps insisted in interfering with design, with the result that progress and output were adversely affected. In numerous cases its wishes were followed, such as the change over from the Hotchkiss to the Lewis gun, the lengthening of the Mk. V. by 6 ft., the turning down of the G.C. Mk. II., and the Mk. IX. machine built to its requirements, and the results were, to say the least, serious.

However, Col. Fuller makes no comment on these points, but doubtless he would agree that in the future the Tank Corps in the field should confine itself to the problem of fighting the machine most effectively, and to giving the fullest possible information to the Headquarters Staff on which it may base its tactical requirements for the future classes of machines, these requirements to be conveyed to the designing department. How far such requirements can be met is for the designing and production departments to decide.

Much has been said about the use of tanks in small numbers at the battle of the Somme, and Col. Fuller is evidently of opinion that, had we held them back until large numbers were available, the element of surprise would have been so great as to have led to an overwhelming victory. The same might be said of the German use of gas for the first time against the Canadians. Personally, the present writer does not hold this view. A new weapon that is going to produce an overwhelming effect requires not only its use on a large scale, but also close co-operation with all other arms. This requires time and elaborate training, and training without the experience of actual battle is apt to be very misleading.

Mk. IV. tanks successfully took part in the decisive battles of the summer and autumn of 1918. It was this mark of machine that in 1917 the Tank Corps refused to accept, considering it useless. A little training in the proper way to fight with the new weapon had made all the difference. It was the Mk. IV. tank which carried out the brilliant operations with the Canadians in crossing the Canal du Nord in September, 1918 (see pp. 268–69). The officer in command of the Canadians after the battle sent for the officer in charge of these tanks and complimented him on the handling of the "new" type of tank and on the way in which all objectives were reached; the officer was silent, for they were the old Mk. IV. machines. The Mk. V. machine was a very great advance on the Mk. IV., but the greatest improvement of all was the realisation of how to use the new weapon in co-operation with the infantry.

Col. Fuller's book naturally deals chiefly with the fighting tank, and he clearly sets forth the claims of armour propelled by petrol as a protection and means of transport for the infantry against the machine-gun; but, as the author also points out, the German offensive of March, 1918, came to an end not so much on account of our resistance as because of the impossibility of bringing up artillery and supplies fast enough by the limited roads. The army of the future will be independent of roads and rails. Its artillery, supplies of shells, food, ambulances, etc., will be moved by petrol and caterpillar tracks.

The chapter on scientific warfare makes interesting reading. It might lead one to suppose that the wars of the future will be waged between small but highly trained armies, and that civilians will be carefully evacuated and safeguarded. The lesson of the late war seems to show that it will be impossible to protect civilians and increasingly difficult to discriminate between the trained warrior and women and children. The use of gas over large areas, of explosive dropped by aircraft, of huge tanks and tractors dashing over hill and dale, in their course passing over hamlets and villages, seems to make the lot of the non-combatant an unenviable one. Possibly this is all for the best, and certainly so if it acts as a deterrent to future wars.

In conclusion, one must say that the book is most excellent reading and remarkably free from controversy or axe-grinding. It has been said that the indication of the object of a war book can be got from the frontispiece. Many have a portrait of the writer, but this starts with a picture of the weapon which had such an effect on history, and the book is a valuable tribute to it (see p. 48).

Physiology of Farm Animals.

Physiology of Farm Animals. By T. B. Wood and Dr. F. H. A. Marshall. Part i. *General.* By Dr. F. H. A. Marshall. Pp. xii+204. (Cambridge: At the University Press, 1920.) Price 16*s.* net.

SUCCESS in the rearing and feeding of animals depends to a large extent upon the practical application of the principles of physiology. Yet, although the breeding of farm animals and the production of meat and milk are of such great economic importance, the study of the physiology of farm animals has received comparatively little attention. The appearance of this text-book is, therefore, welcome. The reputation of the writers is likely to secure a wide use of the book in agricultural teaching centres.

The first volume deals with the general principles of physiology. It is lucidly written, and the illustrations are well chosen. The parts of the subject most fully treated are those which are of special practical importance, viz. the digestive system, the organs of locomotion, and the organs of reproduction. A clear account is given of the digestive system. The chapter on the organs of locomotion contains a very useful

description of the feet and legs of the horse, and the nature and causes of certain common ailments are indicated. The last two chapters, dealing with reproduction, are the best in the book. In addition to giving in a small compass and in an easily understood form all that is known of practical importance, they contain many suggestions that should be of great value to the breeder. A chapter on heredity would have added to the value of the book.

The other parts of the subject are dealt with more briefly, yet in sufficient detail to give the student of agriculture a working knowledge of the subject for all practical purposes.

In a few instances too little attention has been given to recent literature. The use of the term "amides" as covering the non-protein nitrogenous substance of feeding-stuffs is unfortunate. Although the term was used in this sense by certain of the older writers, it is no longer appropriate, since it is now known that the greater part of the non-protein nitrogenous substances consist of amino-acids, which, instead of being "of little importance as constituents of food," are as valuable as protein. The views put forward with regard to the metabolism of creatine and creatinine, which are largely those advanced by Mellanby some years ago, take no account of the work that has been done during the past ten or fifteen years. There is now no doubt that muscle, and not liver, is the chief seat of metabolism of both creatine and creatinine, and there is no experimental evidence in support of the view that creatine is formed from creatinine. The statement that creatine is found in the urine only in pathological conditions is scarcely correct, at least for farm animals. Creatine is found in the urine of the fowl, where it replaces creatinine, and it is a normal constituent of the urine of ruminants.

These, however, are points of minor importance so far as the student of agriculture is concerned. They are likely to be treated more fully in the second volume dealing with nutrition.

Chemical Text-books.

(1) *Laboratory Manual of Elementary Colloid Chemistry.* By Emil Hatschek. Pp. 135. (London: J. and A. Churchill, 1920.) Price 6s. 6d.

(2) *Chemistry for Public Health Students.* By E. Gabriel Jones. Pp. ix+244. (London: Methuen and Co., Ltd., 1920.) Price 6s. net.

(3) *Elementary Practical Chemistry. For Medical and other Students.* By Dr. J. E. Myers and J. B. Firth. Second edition, revised. (Griffin's Scientific Text-books.) Pp. viii+194. (London: Charles Griffin and Co., Ltd., 1920.) Price 4s. 6d.

(4) *Qualitative Analysis in Theory and Practice.* By Prof. P. W. Robertson and D. H. Burleigh. Pp. 63. (London: Edward Arnold, 1920.) Price 4s. 6d. net.

(5) *Practical Science for Girls: As Applied to Domestic Subjects.* By Evelyn E. Jardine. Pp. xiii+112. (London: Methuen and Co., Ltd., 1920.) Price 3s.

(6) *Acids, Alkalis, and Salts.* By G. H. J. Adlam. (Pitman's Common Commodities and Industries.) Pp. ix+112. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

(1) GRAHAM'S pioneer work on colloids is bearing rich fruit to-day, and colloid chemistry is becoming more and more important in theory and in practice. There are, of course, several text-books dealing with the subject generally, and giving descriptions of methods used in preparing colloidal substances. Mr. Hatschek himself is known as the author of one of these, and as the annotator of another, besides being the writer of a notable series of articles on colloids. There is, however, no laboratory manual similar to the present work. To expound the theory of the matter, lectures are good things, and books necessary; but the laboratory remains always the "forecourt of the temple" of colloid philosophy; it is only there that the student gains real familiarity with the characteristic properties of colloidal substances. And in the laboratory a well-devised series of practical exercises is invaluable for economising the worker's time, sparing his temper, and leading him to good results. The author's aim has therefore been to give "accurate and very detailed" directions for carrying out the fundamental operations. He is qualified to write a manual based upon personal experience of the special difficulties met with in the practice of this branch of chemistry, and he has done it very well. Both students and teachers have reason to be grateful to him.

(2) This, also, is essentially a laboratory guide. It is intended for students reading for the diploma in public health, and is therefore concerned generally with foodstuffs, water, alcoholic beverages, sewage effluents, air, and disinfectants. After two introductory chapters explaining the principles of gravimetric and volumetric analysis, the important foodstuffs milk, butter, and margarine are dealt with. Facts as to the chemical composition of these are given, and the legal enactments relating to the sale of them, together with the usual methods of analysis adopted. Then follow chapters on the other articles mentioned. Naturally in a book of only 240 pages some of the subjects

cannot be treated very fully. The information given, however, is accurate, and, whilst the book is readable, it is by no means superficial. Indeed, for a work of its scope it is substantial, and the reviewer has formed a very favourable opinion of it. One of the best sections is the chapter on air, but all are good. A number of examination questions are included.

(3) Dr. Myers and Mr. Firth's little book has become favourably known as a convenient introductory work on practical chemistry. The ground covered is elementary qualitative and quantitative analysis, including an outline of simple gas analysis, with methods for making "preparations" and for identifying the commoner organic compounds. It gives the requisite information concisely, and can be recommended as a suitable initiatory book for medical and pharmaceutical students.

(4) Messrs. Robertson and Burleigh's book is of a more advanced type than the foregoing. It treats of qualitative analysis only, but aims at giving the student a thorough grounding in this subject. The authors rightly hold that qualitative chemical analysis, intelligently taught, is of great value in laying a good foundation for a knowledge of the general chemistry of the metals and in illustrating the more important types of chemical reactions. Their method is to familiarise the student with these types (replacement, decomposition, oxidation, and reduction), and thus to enable him to see how they are applied to the problems of systematic analysis. They discard "dry" tests (apart from flame reactions) as being "tedious, often ambiguous, and misleading." They look with disfavour upon the practice of describing in detail, with equations, the individual reactions of the metals. The practice, they contend, is "pernicious and demoralising"; and the student, in the end, "simply copies into his notes what he sees in his text-book." It is by no means clear why this should be so. Surely it is the part of a capable teacher to find out, by a few suitable questions, whether a student really understands what the equations signify? If this is done there appears to be no particular objection to describing the individual reactions, and such a course simplifies the work of explanation. But be that as it may, there is no doubt that the student who works intelligently through the book under notice should obtain a good grasp of the matter. The questions propounded at the end of the sections will search out his weak points.

(5) This little book contains instructions for performing a series of simple exercises in physics, chemistry, and bacteriology. As occasion offers, the principles under discussion are applied to, or exemplified by, domestic subjects. Thus, having learned various methods of determining specific gravity, the student uses some of them to find the density of milk. In connection with thermometry she learns how to use a clinical thermometer. In the chemistry exercises she is taught how to make soap, how to remove stains from calico, and so on.

The exercises are carefully graduated, and, on the whole, are well calculated to stimulate the pupil's interest. Here and there the text needs a little revision. Thus the experiment (3) on p. 45 is meaningless as it stands. A weighed quantity of household "blue" is mixed with water, the mixture evaporated to dryness, and weighed. The student is then asked to state the percentage of "blue" dissolved! Again (p. 59), permanently "hard" water is directed to be made by dissolving *common salt* in distilled water. Then, after the naïve remark that "we have used salt because it is convenient," the pupil is taught how to "soften" (such) permanently hard water by means of washing-soda. These exercises should be revised; they do not bring out the essential fact that it is the soluble salts of calcium and magnesium, not those of sodium, that cause permanent hardness. "Of the nitrogenous foods there are protein, water, and salts" (p. 70) is a cryptic saying; and it is not the only one. The impression given is that the author occasionally gets a little out of her depth; but the book as a whole will be found quite useful and convenient.

(6) At first sight the title "Acids, Alkalis, and Salts" appears rather unattractive—except perhaps to the chemist, who knows these products already. Mr. Adlam, however, manages to make quite a readable little volume on the subject. Many valuable works will, alas! always and necessarily be classed with the "books that are no books," since they must give the dry bones of facts, and no space is available for investing these facts with even a bare minimum of literary covering. This book, however, aims at being not only instructive, but also interesting. Though starting with little or no knowledge of chemistry, the general reader will have no difficulty in understanding the text, and will find in it a store of information concerning the acids and alkalis which is none the less trustworthy because it is easily and pleasantly acquired. The book may, in fact, be looked upon as a simple introduction to the subject of industrial chemistry. Incidentally, it may help to prevent other people following the example of the man mentioned by the author, who took his son to the Royal School of Mines to "learn copper," and not to waste his time over other parts of chemistry, because "they would be of no use to him."

Our Bookshelf.

Die Gliederung der Australischen Sprachen: Geographische, bibliographische, linguistische Grundzüge der Erforschung der australischen Sprachen. By P. W. Schmidt. Pp. xvi+299. (St. Gabriel-Mödling bei Wien: *Anthropos,* 1919.)

IN this reprint from *Anthropos* Father Schmidt discusses the structure and classification of the Australian languages. Of these he distinguishes two main divisions, the South Australian and the North Australian. The former comprises the languages of the southern halves of Western and South Australia, of Victoria and New South Wales, and the greater (southern) part of Queensland. The North Australian occupies North-west and Central Australia, the Northern Territory, and Cape York Peninsula. The southern languages are subdivided into twelve groups, the northern into three.

The establishment of the South Australian is based mainly on the likeness of grammar and the occurrence in the languages of similar words for names of parts of the body and personal pronouns. The differences in the various subdivisions are found to run parallel with the sociological grouping. They consist chiefly in the character of the finals, which are vocalic where the purely two-class system and mother-right prevail. In the west, north-east, and centre the finals *l, n, r* are found with the four-class system, and the two-class system in the south-east is found where the languages have final explosives and double consonants.

The northern languages are similarly grouped according to their final consonants. In the north-west and north, consonantal finals are common, around Carpentaria *l, n,* and *r* are found as finals, and vocalic endings are common in Central Australia and Cape York Peninsula. But isolated members of the groups are found all over northern Australia.

Father Schmidt's work is a valuable summary and exposition of the tangle of Australian linguistics. But the nature of the material is so uncertain that there will always be a doubt as to whether the similarities of the South Australian languages here formulated may not be due to their geographical contiguity, one language borrowing vocabulary from others, and all alike gradually assuming the same morphological form.

S. H. RAY.

A First Book of School Celebrations. By Dr. F. H. Hayward. Pp. 167. (London: P. S. King and Son, Ltd., 1920.) Price 5s.

THIS is a sequel to "The Spiritual Foundations of Reconstruction," and shows in further detail how some of the suggestions of that interesting book will work out in practice. It may be recalled that the authors—Dr. Hayward and Mr. Freeman—there insisted on the obviously sound idea that in school education more should be made of the emotional, artistic, dramatic, and social approach. They believe, indeed, in scientific and historical wall-charts, the gist of which seeps in to the mind through the eye; they believe in lessons that appeal to the reason—the lessons which bear so little fruit that many of us are often inclined to disbelieve in them; but their hope is in a vast extension of the principle already embodied in Empire Day, Shakespeare Day, and St. David's Day celebrations. Dr. Hayward looks forward in the present book to a national school liturgy of the Bible, literature, music, and ceremonial. The ceremonials would be predominantly oral rather than visual, consisting largely of reading and recitation, song and story; they will be memorial, expository, seasonal, and ethical. It must not be supposed that the author's suggestions depreciate the appeal to reason or propose to codify the emotions; what is suggested is wise and well thought out. We know a little about schools, and our conviction is that the methods suggested would grip in a way that nothing except the teacher's personal influence has hitherto done. They would grip because they are psychologically sound. The celebrations outlined are skilfully devised, but individual teachers would of course vary them. They deal with Shakespeare, the League of Nations, Democracy, St. Paul, bards and seers, world conquerors, Samson, eugenics, temperance, commerce, summer, flying, Chaucer, Spenser. The author has made a notable contribution to the experimental study of education. To test the value of this contribution is an urgent duty, for the school is not very perfect as it is.

New Zealand Plants and their Story. By Dr. L. Cockayne. Second edition, rewritten and enlarged. (New Zealand Board of Science and Art. Manual No. 1.) Pp. xv+248. (Wellington, N.Z.: Dominion Museum, 1919.) Price 7s. 6d.

THE earlier edition of this book, published in 1910, was described as the first attempt to deal with the plant life of the New Zealand biological region on ecological lines. The second edition is virtually a new book. As an instance, the number of photographs which form so helpful an addition to the text has been increased to ninety-nine, and fifty of these did not appear in the original work. But the author and his subject are the same, and no one is so well qualified to describe New Zealand plant ecology as Dr. Cockayne.

An introductory chapter gives an account of the history of the botanical exploration of the islands from the first visit of Banks and Solander in 1769. Successive chapters are devoted to the various phases of vegetation—the sea-coast, the forests, the grass-lands, high mountains, and others—and a brief account of the vegetation of the outlying islands is given. The author discusses the changes which have taken place in the vegetation since the advent of the British, and strongly opposes the idea that the original New Zealand flora is in danger of being crushed out by European immigrants. On the contrary, practically "no truly

primitive plant formation is desecrated by a single foreign invader." The concluding chapters deal with the division of the islands into botanical districts, and the affinities, origin, and history of the flora. As regards the latter, Dr. Cockayne admits the necessity of great land extension in the Antarctic direction.

Annual Reports on the Progress of Chemistry for 1919. Issued by the Chemical Society. Vol. xvi. Pp. ix+234. (London: Gurney and Jackson, 1920.) Price 4*s.* 6*d.* net.

ONE of the most useful of the publications issued by the Chemical Society is the annual volume summarising the progress made each year in the various main branches of chemistry. With this bird's-eye view of the year's achievements at command, a worker is readily able to survey, in something like proper perspective, the advances made in other divisions of the science as well as in his own.

The period covered by the present volume synchronises with the return of many scientific workers from occupations connected more or less directly with the conduct of war to conditions which, in due time, will no doubt lead to a full resumption of scientific investigation for its own sake. Meanwhile it is too early to expect accounts of many such researches. For the moment, the aftermath of war work is being shown in papers dealing with technical problems on which chemists have worked during the last few years. There is, nevertheless, a fair amount of purely scientific research work recorded. Rutherford's investigations on atomic disintegration are of fundamental importance if the results are eventually confirmed; and other notable pieces of work are the studies on the "poisoning" of palladium as a catalyst by hydrogen sulphide, on the origin of alkaloids from amino-acids, and on fermentation. In the "crystallography" section, it may be noted, a good description is given, with figures, of the principles underlying X-ray methods of exploring crystal structure.

The Ascent of Man: A Handbook to the Cases illustrating the Structure of Man and the Great Apes. (London County Council.) Pp. 74. (London: The Horniman Museum and Library, n.d.) Price 6*d.*

THIS little handbook, by Dr. H. S. Harrison, curator of the Horniman Museum, is written in simple language, and admirably suited to stimulate interest in the recent remarkable progress in our knowledge of the ancestry of man. The bibliography with which it concludes will also be helpful to those who wish to pursue the subject further. Dr. Harrison emphasises the fact that man must be traced back to small arboreal mammals, and well observes: "It is scarcely too much to say that if the earth had borne no trees, there would have been no men." His anatomical descriptions are made readable and interesting by his frequent references to habits and modes of life.

Relativity and Reality.

No one would wish to strain at a gnat. If the relativist finds it convenient to make the time-axes of his four-dimensional medium the pure imaginary direction by writing $t=\tau\sqrt{(-1)}$, that would appear to be a matter of indifference, so long as for each coordinate a single line or axis still suffices to indicate the values that x, y, z, and τ can bear. But the matter becomes complicated as soon as we project in oblique directions. Thus take the equations of the "restricted" relativity theory,

$$x=\beta(x'-ut'), \quad t=\beta(t'-ux'), \quad \beta=(1-u^2)^{-\frac{1}{2}},$$

which upon substitution become

$$x=\beta(x'-iu\tau'), \quad \tau=\beta(\tau'+iux'),$$

and these can be written

$$x=x'\cos\theta-\tau'\sin\theta, \quad \tau=x'\sin\theta+\tau'\cos\theta,$$

if $\tan\theta=iu$.

Thus (x, τ) (x', τ') are co-ordinates of the same point projected upon different axes, but not in any real direction. According to this system, A can grasp B's scheme of space-time only when he generalises his own x, y, z, τ, so that each of them stands for an unrestricted complex variable. But such a removal of restriction cannot be pictured without allotting a whole plane to each variable, and that means doubling our whole apparatus of representation and a description of events in terms of not fewer than eight real dimensions. Surely no physicist can be expected to take the system seriously.

The mathematician does not seem to be aware that he is asking one to swallow a camel. Thus in Prof. Eddington's recent book, "Space, Time, and Gravitation," we read (p. 48): "The observer's separation of this continuum into space and time consists in slicing it in some direction . . . clearly the slice may be taken in any direction; there is no question of a true separation and a fictitious separation." But there is the qualification, which surely deserves mention, that every real direction must be excluded, since the angle θ is necessarily imaginary, because β, which is greater than unity, is its cosine. The original passage from (x, t) to (x', t') is real, and we get back to reality by slicing in an imaginary direction with respect to an imaginary axis. The device should be classed with the focoids, those two imaginary points at infinity where any two concentric circles touch. They recall to the mathematician's mind certain algebraic forms, but have no other actuality whatever. The point I would make, however, is this: If this analogy is dropped, the idea of time as a fourth dimension is not in any way advanced by the interpretation of the equations above from the position it has occupied since the days of Lagrange.

R. A. SAMPSON.

Royal Observatory, Edinburgh, July 26.

An Attempt to Detect the Fizeau Effect in an Electron Stream.

WITHOUT in any way touching the theoretical aspect of the case, it seems worth while to put on record the null result of an experiment to see whether the Fizeau effect was present in the case of a beam of light passing along a rapidly moving stream of electrons.

A pair of Jamin plates giving a separation of the

interfering beams of 33 mm. was set up so as to produce achromatic fringes from the light of a mercury-vapour lamp.

Two tubes each about 100 cm. long, with worked glass plates cemented on the ends, were placed parallel, one in each of the interfering beams. Each tube was evacuated, but one contained a glowing cathode and a cylindrical anode which were connected to an alternating source of potential capable of delivering about 20 milliamperes at 100,000 volts, or alternatively 200 milliamperes at 5000 volts, these two potentials corresponding to electron velocities of about 2×10^{10} cm./sec. and 4×10^{9} cm./sec. respectively.

The method of experiment was to produce wide fringes in the observing telescope, and, by means of two tapping switches, to turn on first the filament-heating current and then the applied potential. In no case was any shift or certain broadening of the fringes observed.

The main difficulty in the experiment was the frequent fracture of the necessarily small glass tube employed as the result of the great heat dissipated inside.

The Physics Laboratories, The University, Leeds.

Plant-life in Cheddar Caves.

WHILE recently visiting the famous caves at Cheddar I noticed small patches of moss-like vegetation growing near the electric lamps used to illuminate the caves. The caves extend a long way into the hill-side, and, as the entrances are but small, daylight penetrates into them to a very short distance only. They are lighted by wire filament electric lamps, of which some are hung from the roof, but many are laid upon their sides in the deep natural recesses, and, in order better to illuminate the formation and bring up the beautiful colouring and folding of the stalactites, are provided with reflectors. It was close against some of these lamps that I noticed the patches of vegetation, and they looked so strange that I asked the attendant if they had been placed there as an experiment His answer was that they had not, and that he himself had noticed them growing near the lamps.

It seems to me to be curious that this vegetation should be flourishing under such absolutely artificial conditions where there is no trace of daylight. How the spores got so far in is also an interesting point, but possibly they were introduced by dirty spades used when the workmen were digging out the latest extension of the caves.

I should be glad to know if this curious phenomenon has been observed before, and what kinds of plant-life succeed in these unnatural conditions. As one of the excursions during the forthcoming meeting of the British Association at Cardiff will be to the Cheddar Caves, perhaps a botanical visitor will identify the growth and communicate his conclusions to NATURE.

LOUGH. PENDRED.

The Diamagnetism of Hydrogen.

IN a letter to NATURE of July 22 (p. 645) Dr. Ashworth discusses the atomic diamagnetism of liquid and gaseous hydrogen on the hypothesis that diamagnetism originates from rotations or oscillations of the paramagnetic atom or molecule. He ignores, however, the case of atomic hydrogen in normally saturated hydrocarbons given in my letter of July 8 (p. 581). The atomic susceptibility of hydrogen in these compounds is *constant and equal to* -30.5×10^{-7} *at room-temperature.* Onnes and Perrier (Proc. Amsterdam Acad., vol. xiv., p. 115, 1911) have shown that the specific susceptibility of liquid hydrogen is -27×10^{-7}, with a probable error of 10 per cent., so that there is little difference between this value for hydrogen at a temperature less than $-253°$ C. and that derived from the hydrocarbons at room-temperature. According to the kinetic hypothesis of Dr. Ashworth, the paramagnetic atom will appear diamagnetic only if its oscillations exceed 130° on either side of the position of rest, and oscillations of this nature (or complete rotations) must be common to all the hydrogen atoms in any normally saturated compound. This, I think, Dr. Ashworth will scarcely admit is plausible.

Moreover, consider the general case of crystallisation of a diamagnetic substance. The specific susceptibility of the liquid may be less than or greater than that of the crystals, but each is diamagnetic (Ishiwara, Science Reports, Tôhoku, vol. iii., p. 303, 1914; Oxley, Phil. Trans. Roy. Soc., vol. ccxiv., A, p. 109, 1914). Therefore the oscillations of the atoms which appear diamagnetic must be at least 130° on either side of the position of rest, even in crystals—a conclusion which is scarcely consistent with the view that crystalline symmetry is in part determined by the electronic configuration of the atom.

Loss of Fragrance of Musk Plants.

IT is important to ascertain whether the loss of scent which has been noticed lately in the musk plant (*Mimmulus moschatus*) in certain areas is of general occurrence throughout the country.

There is no doubt that in many cases the descendants of musk plants which used to form such fragrant inhabitants of our cottage windows have lost the power of producing the peculiar musk-like scent. An important character has dropped out of the musk plant's hereditary equipment, and it becomes a matter of interest to know to what extent and in what manner this has come about.

If any plants can be found which still retain the old scent, intercrossing between these and the scentless variety would probably give genetic results of interest.

Meteorological Conditions of an Ice-Cap.

IN NATURE of July 29 Mr. R. M. Deeley criticises Prof. Hobbs's terminology in describing the meteorological conditions of an ice-cap as anticyclonic. He arrives at the conclusion from Prof. Hobbs's statements that low pressure exists at the centre. This is scarcely necessary.

The high pressure of an anticyclone in temperate regions is maintained by the descent of air in the centre drawn from the upper atmosphere; this compensates for the surface outflow due to the disturbing of the geocyclostrophic equilibrium by surface friction. The same conditions, *i.e.* the surface outflow and the central descent of air, exist in Prof. Hobbs's polar ice-cap anticyclone; the only difference is the physical origin.

In stating that the outflow of air over an ice-cap produced a vacuum which was filled by inflowing air from above, Prof. Hobbs was only describing in separate detail what is really a continuous process, no vacuum ever actually existing.

R. F. T. GRANGER.

Lenton Fields, Nottingham, July 30.

The Research Department, Woolwich.

By Sir Robert Robertson, K.B.E., F.R.S.

I.

Explosives Section.

THE Research Department at Woolwich has been in existence under various titles since 1900. Prior to 1914 the staff was small; thus for the seven years preceding the war the chemical branch had a staff of eleven chemists only, and the metallurgical branch of four.

The subjects occupying the chemical staff before the war were connected with the stability of explosives, the investigation of new explosives (such as tetryl, for which a manufacturing process was worked out and issued to a Government factory), and research on the properties of explosives and on the means of initiating them in Service components. These researches proved to have a double importance, in that they not only enabled immediate answers to be given to many questions that arose early in the war, when there was no time for prolonged research, but also afforded the staff the training necessary to meet the demands which became urgent on the outbreak of hostilities.

After the beginning of the war the increase in work imperatively demanded a larger staff, and more chemists were appointed, until at the beginning of 1917, the home supply having failed, permission was obtained to withdraw from France members of the Special Brigade, R.E., of whom more than thirty were transferred to the Department. Finally, the chemical staff numbered 107 chemists and physicists distributed in an organisation which had been gradually evolved, comprising sections for dealing with the different classes of work, such as organic chemistry, physical chemistry, analytical and general chemistry, physical investigation, calorimetry, stability, pyrotechny, applications of high explosives, fuse design, and records.

With increasing work and staff, new buildings for explosives investigation became necessary, and new laboratories were erected, including a well-appointed building (Fig. 1) for physico-chemical research, embodying many of the ideas of Prof. Donnan, and a new range of factory buildings and houses for a variety of specialised work. Climatic huts for storage trials under dry and moist conditions, which have always been an important feature of the Department, were increased in number. In the explosives section the laboratories occupy a space of 64,272 sq. ft., and the buildings for experimental work on a larger scale 38,170 sq. ft. The Department's facilities for testing processes evolved in the laboratory on the semi-manufacturing scale have proved of the utmost value, affording confidence as to the practicability of processes on the full scale.

The Research Department acted as a central bureau for explosives research required by the Navy, Army, the Air Service, and the Ministry of Munitions. Many subjects were referred to it by the Ordnance Committee. Its work is embodied in official minutes and in collected researches termed R.D. Reports.

Trinitrotoluene.—One of the first subjects undertaken after the outbreak of war was the provision of an efficient and rapid process for the manufacture of T.N.T., especially without the use of oleum. From the results of a large series of nitrations in the laboratory, a process was evolved characterised by several novel features, and this was put to the proof on the semi-industrial scale, a plant being designed and erected in the Department (Fig. 2) for the nitration on the quarter-ton scale, with appropriate arrangements for the mixing and concentration of acids. This small plant substantiated in a remarkable manner the process evolved from the laboratory work, and from the start turned out T.N.T. of good quality. The scheme of temperature-rise, the composition of the acid mixture, the nitration in cycles, the process of "detoluation," and other features of the process found immediate application in the large Government factories that were designed and erected by Mr. Quinan, and also in numerous private works built at this time.

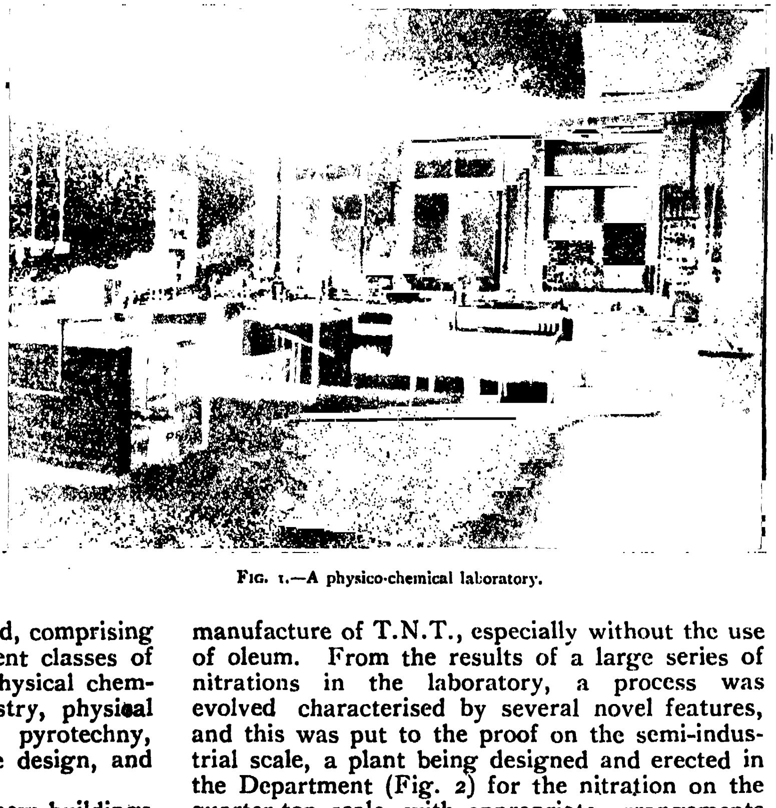

FIG. 1.—A physico-chemical laboratory.

These features have been little altered by later experience. Chemists were trained on this small plant for the purpose of starting Government

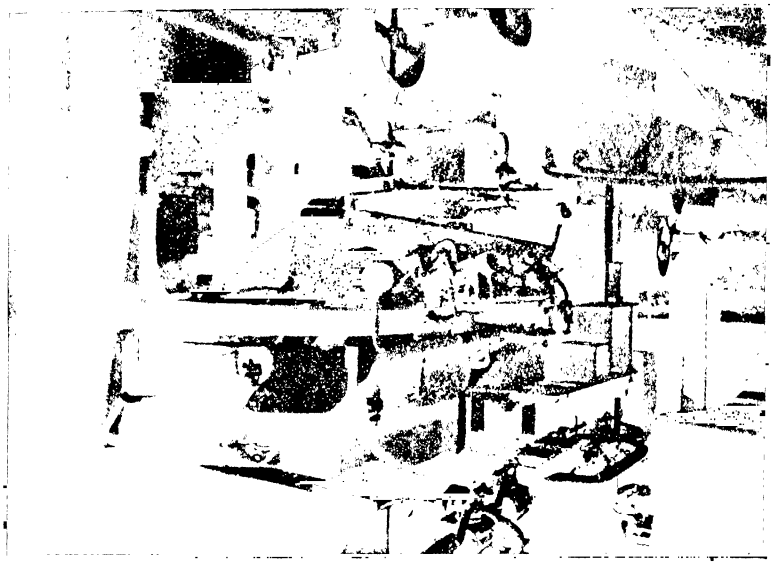

FIG. 2.—Small nitrating plant used to demonstrate the T.N.T. process.

and private factories, and for a time a few tons a week of the product were purified by alcohol-benzene in another plant erected in the Department to supply the Service with high-grade T.N.T. for exploders.

A study of T.N.T. in all its aspects was undertaken. Much attention was given to the chemistry of T.N.T., the proportions in which the isomers occur in the crude product being determined by thermal analysis, and investigations made on their interactions, stability, sensitiveness, heat values, and explosive properties.

Amatol.—As it soon became evident that the supply of the high explosives in use, lyddite and T.N.T., would not suffice, the Department put forward mixtures of ammonium nitrate and T.N.T., the amatols, as a result of study of their properties and of the violence they exhibited in shell-bursting trials. Gun trials substantiated the trials at rest, and their adoption quickly followed. Various methods of filling these mixtures into shell were at this time worked out, many of which have since been applied on the very largest scale.

It was found that 80/20 amatol (80 parts of ammonium nitrate to 20 of T.N.T.) was less easy to bring to detonation than lyddite or T.N.T., and required special arrangements in the train of initiation of detonation. These were successfully devised, and good and trustworthy detonation of our shell was secured. An illustration is here given (Fig. 3) of the fragmentation of an 18-pr. shell filled with 80/20 amatol.

As 80/20 amatol is practically smokeless, the constituents being arranged for complete combustion, mixtures producing a white smoke for indicating the point of burst were worked out for inclusion in the shell-filling. Ultimately, amatol became practically the only explosive for land and aerial warfare, and justified its choice based on the early estimate of its properties and capabilities. In 1917 the production was at the rate of about 4000 tons a week. It is economical in that it makes use of a cheap ingredient, and has explosive properties that render it very suitable for the purposes for which it is used.

The Department continued the study of amatol especially with regard to its chemical stability and compatibility with the various materials with which it came into contact. Certain impurities in ammonium nitrate were discovered to be objectionable, and investigation of this led to an improvement in the purity of the ammonium nitrate supplied.

R.D.B. Cordite.—When the available quantity of acetone became quite inadequate for the cordite required, the Department brought forward a new type of cordite (Research Department "B" or R.D.B. cordite) as a result of experimental incorporations with ingredients chosen to give the same ballistics as ordinary cordite. It could be

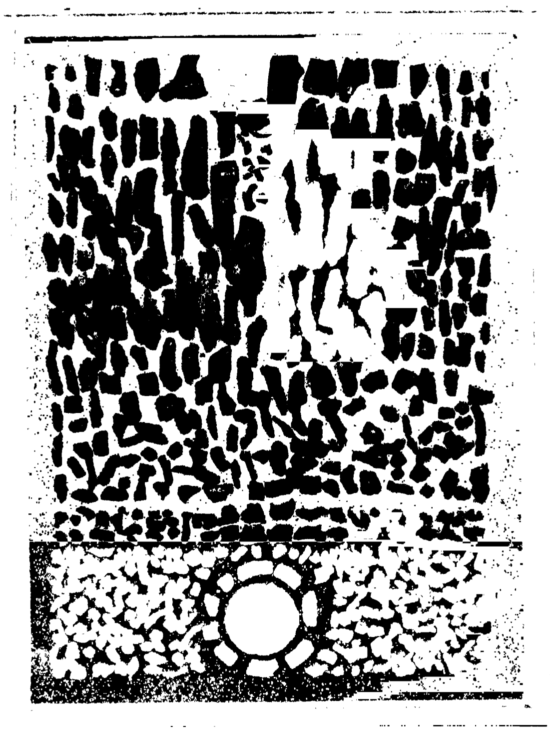

FIG. 3.—Fragmentation of 18-pr. shell by 80/20 amatol.

made with no alteration in the plant required for the manufacture of propellants. Instead of acetone, the solvent employed was ether-alcohol,

and instead of gun-cotton, a lower nitrate of cellulose was used. The great factory at Gretna, also built by Mr. Quinan, manufactured R.D.B. cordite exclusively, and this soon became the only propellant made in this country for the Land Service. It was produced both by Government and by private firms in enormous quantities.

The need for ether and alcohol for this propellant led to the restrictions imposed on alcohol.

The recovery of the new solvent presented new problems, and investigations on these were undertaken, which have increased our knowledge of the principles underlying the absorption of vapours.

As difficulties arose in the gelatinisation of the special nitrocellulose required for this powder, the Department continued its studies on the viscosity of cellulose and nitrocellulose with important results, which formed the groundwork of the procedure adopted in supply for obtaining uniformity in the cotton used in the nitration, and a diminished usage of solvent in the incorporation.

Other Explosives.—Many other explosives for special naval and land purposes were put forward by the Department and adopted by the Service after their properties had undergone investigation.

Design of Ammunition.—A feature of the work is the close connection between mechanisms connected with ammunition and the utilisation in them of explosives the properties of which have been found specially suitable. The Department was fortunate in the success which has attended its percussion fuse (No. 106), which played such an important part in the war.

Pyrotechnics.—New demands occasioned by the war led to the study of compositions for pyrotechnic and incendiary purposes and to chemical investigations on the compatibility of the ingredients used. Many new compositions were devised and adopted for signals, stars, and incendiary shell.

Study of the Theory of Explosives.—The study of the chemical constitution of nitro-compounds has been referred to; but a large amount of information the usefulness of which has been reflected on Service requirements has accrued from the development of systematic work on such subjects as the calorimetry of explosives, for which new methods and apparatus have been devised, their sensitiveness, their rates of decomposition and of detonation, and the pressure of the blow they develop. The last was an extension of the work of the late Prof. B. Hopkinson, and has been fruitful in advancing knowledge of theory as well as in providing instruments for quantitative registration of the effects of explosives contained in Service components.

General.—The high quality and efficiency of our ammunition, in spite of shortage and the need for providing substitutes, have been obtained as a result of the continuous application of chemical and physical research. The research initiated and carried out provided in numerous cases methods for the production of explosives, and demonstrated the conditions for their safe employment; principles of fundamental importance were discovered which were utilised in the designing of ammunition; causes of failure at early stages were discovered, thus avoiding unsatisfactory issues of material; and substitutes and alternatives, without which some of our great war manufactures could not have been carried on, were sought and discovered.

(To be continued.)

The Earliest Known Land Flora.[1]

By PROF. F. O. BOWER, F.R.S.

II.

COMPARISON of these four fossil species from Rhynie with other fossils already known from the early Devonian period shows that a very homogeneous flora existed at that time, consisting chiefly of leafless and rootless land-living plants. These and other characters, such as their large, distal, sometimes solitary, and often forked sporangia, stamp these plants as exceptionally primitive. Among living plants the nearest of kin to them are clearly the Psilotaceæ, a family which has long presented a problem in morphology and classification. It comprises two living genera, Psilotum and Tmesipteris. Both genera are rootless. Their imperfect morphological differentiation is shown by the fact that botanists are not yet agreed whether their lateral appendages are to be held as truly foliar or not. Psilotum is native throughout the tropics, and is represented by two well-marked species. The commonest, *P. triquetrum*, has upright and shrubby aerial shoots, with radial construction and frequent bifurcations. These spring from leafless underground rhizomes, profusely bifurcated. They are covered with rhizoids, and contain a mycorhizic fungus. On the lower part of the aerial shoots simple spine-like leaves are borne, but towards the distal ends these are replaced by forked spurs, between the prongs of which a synangium, usually with three loculi, is seated. The aerial shoot is traversed by a vascular strand consisting of xylem in the form of a hollow many-rayed star, with sclerotic core, and branch-strands run out to the appendages. The whole is covered by epidermis with stomata, and the cortex provides the photosynthetic tissue. Tmesipteris is represented by only one species, limited to Australasia. It grows usually among the massed roots that cover the stems of tree-ferns, but sometimes upon the ground. Its general form is like

[1] Discourse delivered at the Royal Institution on Friday, April 30. Continued from p. 684.

that of Psilotum, but the underground rhizomes are longer and the appendages larger, while only two loculi are usually present in each synangium. Clearly the form and vascular structure of these plants are generally like those of the Rhynie flora.

Until quite recently the Psilotaceæ remained the only living Pteridophytes of which the life-cycle was still incompletely known. In all the other groups the regular alternation of two generations had been demonstrated; one is the prothallus, which is sexual, and the other the established plant, which is non-sexual. In the Psilotaceæ also the plant as above described is the non-sexual generation, but hitherto the form or even the existence of the sexual generation remained problematical. Since 1914 the prothalli of both genera of the Psilotaceæ have been discovered, and their structure has been demonstrated by Darnell-Smith, Lawson, and Holloway; and so the very last of these life-histories has now been completed. It turns out that the prothallus of the Psilotaceæ is similar in its general characters to those of other archaic Pteridophytes, being colourless, and living in humus by means of fungal nourishment. In fact, these plants conform in their life-cycle to what is seen in the Lycopods and in the primitive Ferns. Analogy with the living Psilotaceæ makes it highly probable that these early Devonian plants also showed alternation. Though this has not been demonstrated for them, their preservation is so perfect that even the delicate prothallus may yet be revealed as the reward of further search.

The interest of the recent work on the modern Psilotaceæ centres not so much in the details of the prothallus as in their embryology. It has been shown by Holloway that the embryo of Tmesipteris is rootless from the first. This suggests that the rootlessness is primitive, and not the result of reduction. Since the Devonian plants were rootless also, it seems probable that this state was characteristic of such early plants of the land. Further, the existence of Sporogonites, and the very moss-like structure of its sporangium, together with its similarity to the sporangia of Rhynia and Hornea, seem to link up the latter naturally with the Bryophytes, which are also rootless. In fact, we see before us a flora of rootless plants, which raises afresh the question of the first establishment of the neutral generation as an independent, soil-growing organism. It originates in every case within the tissue of the sexual plant, and is at first dependent upon it. This condition is seen in the embryo of Tmesipteris, with details not unlike those of the Anthoceroteæ. How, then, did it first establish itself independently upon the soil?

This question was first raised long ago by Dr. Treub, the brilliant director of the Botanic Gardens at Buitenzorg. He suggested that in the evolution of land-living plants a rootless phase would naturally precede the full establishment of the sporophyte in the soil. He saw this reflected in the embryonic state of certain Lycopods, where a parenchymatous tuber precedes the establishment of the rooted plant. It is attached to the soil by rhizoids, and contains a mycorhizic fungus. This tuber Treub styled the "protocorm." He regarded it as a general precursor of the established leafy plant in descent. During the war new examples of this protocorm-stage were described by Holloway, which show the condition in its most pronounced form. In *Lycopodium laterale* it constitutes the whole plant-body for the first season. It bears numerous protophylls, and may even branch, and reproduce itself vegetatively. It is only later that the leafy shoot and lastly the root are formed. The fact that Hornea shows a similar tuberous swelling at the base of the rootless plant, and retains it even in the adult state, brings the added interest that a permanent protocorm figures in the earliest known land flora. Its antiquity is thus undoubted. But the Devonian plants do not all show it in a distended form. The tuberous swelling is not conspicuous in Rhynia or in Asteroxylon, and it is significant that in the living Tmesipteris the rhizome is cylindrical. These facts indicate that the distended protocorm is neither an obligatory nor a constant feature.

It will not be necessary to do more than refer briefly to the controversy whether the appendages of the Psilotaceæ are truly leaves or branches. The fact suffices that the question has been in debate, and that similar questions arise in relation to these fossils of the Devonian period. In them it is impossible to assign the name "leaf" to any definite part in the full sense in which it is used in the higher vascular plants. The difficulties of their morphological analysis and their rootlessness are in themselves evidence of the primitive state of these fossils. We are, in fact, in the presence of what evolutionists call "synthetic types"—that is, such as link together groups which have diverged. The early Devonian plants and the Psilotaceæ show us just those forms which might have been anticipated as a consequence of comparative study, and some of their characters were actually forecast by Dr. Treub.

Though it may be difficult to place the parts of these synthetic types in the categories of stem, leaf, and root, as those terms are applied to more advanced forms, still they will serve to illuminate the probable origin of these parts. The rhizomes of Asteroxylon suggest an origin of roots from branched, leafless rhizomes. Its "leaves" suggest a relation with the leaves of Lycopods; but its most significant feature is the branch-system ascribed to Asteroxylon, bearing the distal sporangia, which is so like that already described for the enigmatical Carboniferous fossil Stauropteris. This comparison has already been pointed out by Kidston and Lang. On the other hand, approaching the question from the side of the living Ferns, I indicated in 1917 that "the distal and marginal position of a sorus, often monangial, is prevalent among primitive Ferns, and that more complex sori are referable in origin to it." Comparison of the distal sporangia of

the Psilophytales with those of Stauropteris, Botryopteris, the Ophioglossaceæ, Osmunda, and the Schizæaceæ, gives a sequence which sketches in broad lines, though not monophyletically, a probable origin of marginal sporangia for the Ferns. It is accompanied by reduction of size and spore-number in the later and derivative types, which is continued on to the most advanced of living Ferns. A reduction of the distal branchlets to a single plane, and the webbing of them laterally together, would give a type of sporophyll and fructification known in certain primitive Ferns. But if this were the real course of their evolution, the sporophyll so constructed would be a different thing from the "leaves" seen in Asteroxylon. This was the vision of the prophetic Lignier, who has not lived to see his ideas tested by these new discoveries. But such comparisons still leave in doubt the origin of the axis in fern-like types. It is not clear yet how near the truth for them my suggestion of 1884 may be: that "the stem and leaf would have originated simultaneously by differentiation of a uniform branch-system into members of two categories." Nevertheless, the important new fact, which now gives reality to this theory, is that a uniform branch-system has been shown to have existed in these early vascular plants. A sympodial development of it, after the manner shown in the leaves of living Ferns, would provide at least one type of foliar appendage, which would bear a relation to the axis similar to that of the pinnæ to the phyllopodium or Pachis of the leaf.[2]

On the other hand, comparison of the Bryophytes will leave little doubt that the sporangium of the Psilophytales and the sporogonium are kindred structures. If this be so, then we shall see linked together by comparison with these new fossils, not only the sporogonia of Bryophytes and the sporangia of Ferns, but even the pollen-sacs and ovules of Flowering Plants. Long ago it was remarked that the widest gap in the sequence of plants was that between the Bryophytes and the Pteridophytes. It is within this gap that the newly discovered fossils take their natural place, acting as synthetic links, and drawing together more closely the whole sequence of land-living, sporangium-bearing plants. We still await with interest the considered comparisons of the authors of these notable memoirs, though they have already pointed out several fertile lines. But those who have been deeply engaged in comparative morphology may be excused for stating how these new facts strike them. Clearly the morphology of land-living plants is again in the melting-pot. It will emerge strengthened by new and positive facts, and refined by comparisons which can now be based upon solid data, and less than before on mere surmise.

The new facts are thus seen to link the Bryophytes and the Pteridophytes more closely together than ever before. It may be that these two great phyla of land-living plants have themselves diverged from some common source still unknown. But that source is reflected more nearly in these early Devonian plants than in any other known forms. If that be so, whence may these still more primitive plants have sprung? The view has always been entertained that the Algæ preceded land-living plants. For long the fresh-water green Algæ were believed to have provided the source. Latterly from the Continent, but notably also here at home, at the instance of Lang and of Church, the belief has swung round towards marine forms. Highly specialised Algæ flourish on every rocky shore. Some of these show alternation. All are rootless. Some have a differentiation of their branch-system which prefigures the relation of leaf and axis. Not a few of the Red Seaweeds have spore-tetrads borne internally, and located in the ends of specialised branches called stichidia. These are not altogether unlike sporogonia, or the large sporangia of the early Devonian plants. We may well regard it as improbable that any direct transition of such specialised types to a land-habit took place, though this has been hinted at more than once. But at least corresponding features of external differentiation and of spore-production are present in both. Homoplasy may be the real explanation of the likeness, but still the similarity exists.

From what has been said it is clear that during the years of war plant morphology entered upon a new phase. The problems of origin of root and axis and leaf and sporangium have been propounded afresh in terms of the new discoveries. The day is past of that vague surmise on these points which bulked so largely in the discussions of recent decades. It was the paucity of facts that kept opinion in suspense, hovering between rival arguments rather than settling on assured data. Looking back upon the history of that branch of botanical science which is called comparative morphology, there is only one period that can rival the years from 1913 to 1920 in point of positive advance. It is the period which led up to the great generalisations of Hofmeister sixty years ago. In the glories of that work Britain had no direct share, though it was carried out at the very time when Lyell, Darwin, Wallace, Hooker, and Huxley were laying the theoretical foundations which gave their real significance to the discoveries then made by Hofmeister. In the words of Sachs: "When Darwin's theory was given to the world—the theory of Descent had only to accept what genetic morphology had already brought to view." Science, it is true, is cosmopolitan, and should always be held as such. But still we in Britain may feel a legitimate satisfaction that in these recent discoveries, which have transformed the problems of morphology, the material, the observations, and the arguments based upon them are mainly of British origin. The channel of publication of the results, so largely derived by Scottish workers from Scottish material, has naturally been the Transactions of the Royal Society of Edinburgh.

Meteorological Influences of the Sun and the Atlantic.[1]

By PROF. J. W. GREGORY, F.R.S.

THE prospects of long-period weather forecasting and the explanation of major variations of climate appear to rest on two lines of investigation. The effort of the first is to connect changes in the weather with those in oceanic circulation; the second attributes the changes to variations in the heat supply of the sun acting through the atmospheric circulation. Each theory has its own *a priori* probability. The oceanic control of climate has the attraction that each ocean is a potential refrigerator, since it is a reservoir of almost ice-cold water, which, if raised to the surface, must chill the air, disturb the winds, and enable polar ice to drift further into the temperate seas. Hence Meinardus, for example, connected the range of ice in the Icelandic seas and harvests in Germany with variations in the surface waters of the North Atlantic. The alternative theory has the recommendation that, since the earth receives its heat supply from the sun, variation in solar activity is the natural cause of climatic change.

The oceanic theory must be true in part. The abnormal character of some coastal climates is clearly due to the upwelling of cold water under the influence of off-shore winds. Moreover, unusual spells of weather on some of the coasts and islands of the Atlantic follow changes in the quality of its surface water, as proved by Dr. H. N. Dickson for North-western Europe, and by Prof. H. H. Hildebrandsson's demonstration that for fifteen years there has been constant coincidence between rainfall in British Columbia and the weather in the following autumn in the Azores. The alternative theory that the main factor in controlling the temperature of the earth is the varying heat from the sun acting through changes of wind and atmospheric pressure has been mainly advanced by the work of Sir Norman and Dr. W. J. S. Lockyer and of Prof. Frank Bigelow; they are now strongly reinforced by Dr. B. Helland-Hansen, the director of the biological station at Bergen, and Dr. Nansen, who remark that these views have hitherto received but little support.

The important memoir by these Norwegian oceanographers is based on a detailed study of variations in the temperatures of the air and surface waters along the steamer route from the English Channel to New York. Their detailed discussion of the results and associated problems is accompanied by a valuable series of temperature charts of the North Atlantic for the months of February and March from 1898 to 1910. The data are often uncertain, and the inconvenience of the Centigrade thermometer with its zero at freezing point is illustrated by records of water temperature of $-3°$ C. and $-4°$ C., which have to be rejected. Drs. Helland-Hansen and Nansen, after discussion of the theory of oceanic control, reject it as quite inadequate. Thus the chilling effect of the drift of ice into the North Atlantic they estimate as "vanishingly small" in comparison with the heat transported by the air, or even by ocean currents. They consider that, though not yet fully established, the variations of the air temperature preceded, and were therefore not the result of, those of the water temperature. They hold that the variations of temperature require some much greater and more general cause than oceanic variations.

Faith in the meteorological influence of oceanic circulation was greatly favoured by the exaggerated estimates attached to what the authors refer to as "the so-called Gulf Stream." Thus the warmth of the water off the Norwegian coast was attributed to that current even by Pettersson and Meinardus; this conclusion the authors describe as surprising because the evidence of salinity shows that the Norwegian waters are coastal and quite different from those of the mid-Atlantic. This sound criticism of the Swedish and Münster oceanographers renders it the more remarkable that there is no reference, either in the long historical discussion or in the bibliography, to the pioneer work on this subject in the earlier papers by Dr. H. N. Dickson, or to his observations as to the seasonal entrance of the Atlantic water into the North Sea. The authors agree with Schott in terminating the Gulf Stream west of Newfoundland, and calling the current off Western Europe the "Atlantic current," for which Dickson's name of "European current" is more descriptive and definite. The Atlantic is a large mass, and has a whole system of currents, of which the so-called Atlantic current is by no means the largest.

Drs. Helland-Hansen and Nansen, after rejecting the oceanic theory, accept as firmly established the dependence of variations in the earth's temperatures on the solar variations proved by sunspots, the numbers of solar prominences, and terrestrial magnetic disturbances. They point out that the influence of the sun on the weather of any area on the earth depends upon so complex a series of factors that the results at first sight appear inconsistent. The crude expectation that an increase of heat supply from the sun would raise the temperature of the whole earth was early dismissed, for the greater evaporation would lower the temperature on the coastlands by increased clouds, rain, and snow. Blanford pointed out, for example, the see-saw of oceanic and continental conditions; but, though his view has not been fully confirmed, his principle is supported by the proof that regions are oppositely affected by changes in the heat supply from the sun. Bigelow has divided the world into three groups of regions: in the "direct" group the temperature conditions vary directly with the sun; in the

[1] Björn Helland-Hansen and Fridtjof Nansen, "Temperature Variations in the North Atlantic Ocean and in the Atmosphere." Introductory Studies on the Cause of Climatological Variations. Smithsonian Miscellaneous Collections, vol. lxx., Publication 2537. 1920. Pp. viii+408+48 plates.

"indirect" group the variations agree in time, but are opposite in character; in the third, the "indifferent" group, there is no regular correspondence. Sir Norman and Dr. W. J. S. Lockyer have shown that a region may for years belong to the "direct" group, then suddenly become "indirect," and later return to the "direct" group. Drs. Helland-Hansen and Nansen accept this frequent inversion, and also their explanation of the phenomenon.

The authors' instructive study of North Atlantic temperatures therefore strengthens the case for solar variations acting through the atmospheric circulation as the main cause of meteorological changes. To what extent the ocean helps by regulating the air temperature and circulation the authors do not discuss in the present memoir; that and other questions are to be dealt with after further investigations in a series of memoirs to which the present is introductory. The usefulness of the promised memoirs would be increased (should they have as many appendices and supplementary notes as the present) if each were provided with an index.

The Thermionic Valve in Wireless Telegraphy and Telephony.[1]

By PROF. J. A. FLEMING, F.R.S.

THE thermionic valve is an invention which has vastly increased the powers and range of wireless telegraphy. Like many other inventions, the telephone, for instance, it is simple in its essential construction. It consists of a little electric lamp comprising a glass bulb, very highly exhausted of its air, containing a filament of carbon, or better tungsten, which can be rendered incandescent by an electric current. Within the bulb and around the filament are fixed certain metal plates or cylinders, and, it may be, spirals of wire or metal networks called the grid. To explain its origin in its simplest form I shall have to take you back in thought to the days when the physical effects taking place in incandescent electric lamps were first beginning to be considered carefully. In 1883 Mr. Edison for some purpose placed in the glass bulb of one of his carbon filament lamps a metal plate which was carried on a platinum wire sealed through the glass. When the filament was rendered incandescent by a current from a battery, he found that if the plate was connected by a wire, external to the lamp, with the positive terminal of the filament, a small electric current flowed through it, but if connected to the negative terminal no current, or at most a very feeble current, flowed. This new and interesting effect became known as the "Edison effect" in glow lamps, but Mr. Edison gave no explanation of it, and made no practical application of it.

Edison supplied some lamps with plates in the bulb to the late Sir William Preece, and the latter found that the current called the Edison effect current increased very rapidly as the filament was heated to higher and higher temperatures, and that the collecting plate could be placed a long way from the filament, even at the end of a side tube, without altogether causing it to vanish. At a little later date I took up the subject, and one of the first things discovered was that the Edison effect was greatly reduced if that side of the carbon loop filament in connection with the negative pole of the battery was enclosed in a glass or metal tube, or if a sheet of mica was interposed between the filament and the collecting plate. This seemed to indicate that the effect was due to some material emission from the hot filament.

Another fact I observed very soon was that the filament was giving off torrents of negative electricity, and could discharge a positively electrified conductor connected to the plate, but not one negatively charged. Furthermore, I found that the vacuous space between the filament and the plate possessed a curious unilateral electric conductivity for low-voltage direct electric currents, and that even a single cell of a battery could pass a current from the hot filament to the collecting plate if the negative pole of the battery was in connection with the hot filament, but not in the opposite direction. This fact had, however, been previously noticed in another manner by W. Hittorf. These experiments were made in 1888 or 1889, and at that time were not satisfactorily explained.

It was not until nearly ten years later that your distinguished professor of natural philosophy, Sir Joseph Thomson, published accounts of his epoch-making and important researches, in which he proved that the agency we call negative electricity is atomic in structure, and exists in indivisible units now named electrons, which carry a certain electric charge and have a certain mass. These negative electrons are constituents of all chemical atoms. An electrically neutral atom which has lost one or more electrons is called a positive ion, and neutral atoms which have lost or gained electrons are said to be ionised. There are arguments in favour of the view that the majority of the atoms in metals and other good conductors of electricity are in a state of intermittent ionisation, and that intermingled with the atoms or positive ions, say in a wire of copper, tungsten, or carbon, there are electrons which are jumping from atom to atom with great velocity. If we apply to the wire an electromotive force, this causes a drift of these electrons at the instant they are free in the opposite direction to the force (on usual conventions), and this drift or unidirectional motion is superimposed on the irregular motion, and constitutes an electric current. The drift velocity may be very slow compared with the velocity of the irregular motion. The drift motion of the electrons superimposed on the irregular

[1] From a discourse delivered at the Royal Institution on Friday, May 21.

motion may be compared with that of a swarm of bees in which each insect is flying hither and thither rapidly, whilst the whole swarm is being blown by a gentle breeze slowly down a road. If the electrons merely surge to and fro, it gives rise to a form of current we describe as an alternating current, and if they execute this motion very rapidly we call it an electric oscillation.

The reason an electric current produces heat in a conductor is because the drift energy of the electrons is then being continually converted into additional irregular-motion energy in the free electrons and atoms by collisions of electrons with the atoms of the conductor. If, then, the temperature becomes very high—that is, if the irregular electronic motion becomes very great—certain electrons may acquire such velocities that they are flung out from the surface of the wire even against the attraction of the positive atomic ions left behind. If there is no electric force tending to make the electrons move away from the neighbourhood of the hot wire, these electrons constitute a *space charge* around it, and the repulsion they exercise on each other tends to keep other electrons from getting out into the space. Suppose, however, that the incandescent wire is placed in the axis of a highly exhausted glass tube, and is surrounded by a metal cylinder which is kept positively electrified, the electrons move to it, and others then make their exit from the wire. Such a tube with incandescent wire cathode and cold metal plate anode is now called a *thermionic tube*. The steady emission of electrons is called a *thermionic current*. In the case of a tungsten wire brilliantly incandescent *in vacuo* and under sufficient electric force, this current may amount to as much as an ampere per square centimetre of surface. This means that electrons are being flung or pulled out at the rate of millions of billions per second per square centimetre. So soon as Sir Joseph Thomson had proved by experiment that this electronic emission was taking place the explanation of the effects observed in incandescent electric lamps by Edison, Preece, and myself became clear. For in the Edison experiment we have a slow drift of electrons through the carbon filament superimposed on a very rapid and erratic motion, and multitudes of these electrons are escaping from the filament on all sides—just like steam escaping from a porous or leaky canvas steam pipe. If the plate in the bulb is connected to the positive pole of the filament-heating battery, it is positively electrified and it attracts these escaped electrons, and they enter it and drift through the external wire, forming the observed Edison current.

Suppose, then, that we connect the collecting plate by a wire external to the bulb with the negative terminal of the filament, and that we insert in this circuit a battery of a number of cells which can be altered so as to vary the potential of the plate, the said battery having its negative terminal connected to the filament, we then find that a thermionic current flows which can be measured by an amperemeter inserted in the circuit. If we vary the voltage from zero upwards we shall find that the thermionic current increases, but not indefinitely. It soon reaches a value at which no further increase of voltage raises the current. The reason the current does not increase indefinitely is because for each particular temperature of the filament there is a certain maximum possible rate of electronic emission. The electrons are drawn away from the filament at a rate which increases with the potential of the plate up to that point at which the maximum emission rate is reached. The thermionic current then becomes stationary and is said to be *saturated*.

It is remarkable that although this emission of electricity from incandescent substances had been studied for more than a quarter of a century, none of them made any practical application of it prior to 1904. At that date I was so fortunate as to discover a totally unexpected application of this thermionic emission in wireless telegraphy. Before 1904 only three kinds of detector were in practical use in wireless telegraphy, viz. the coherer, or metallic filings detector, the magnetic-wire detector, and the electrolytic detector. The coherer and the electrolytic detectors were both rather troublesome to work with on account of the frequent adjustments required. The magnetic detector was far more satisfactory, and in the form given to it by Senator Marconi is still used. It is not, however, very sensitive, and it requires attention at frequent intervals to wind up the clockwork which drives the moving iron-wire band.

In or about 1904 many wireless telegraphists were seeking for new and improved detectors. I was anxious to find one which, while more sensitive and less capricious than the coherer, could be used to record the signals by optical means. Our electrical instruments for detecting feeble direct or unidirectional currents are vastly more sensitive than any we have for detecting alternating currents. Hence it seemed to me that we should gain a great advantage if we could convert the feeble alternating currents in a wireless aerial into unidirectional currents which could then affect a mirror galvanometer or the more sensitive Einthoven galvanometer. There were already in existence appliances for effecting this conversion when the alternations or frequency was low, namely, one hundred or a few hundred per second. After trying numerous devices my old experiments on the Edison effect came to mind, and the question arose whether a lamp with incandescent filament and metal collecting plate would not provide what was required even for extra high frequency currents, in virtue of the fact that the thermionic emission would discharge the collecting plate instantly when positively, but not when negatively, electrified. Accordingly I appealed to the arbitrament of experiment, and the following arrangement was tried.

Two coils of wire were placed at a distance, and in one of them electric oscillations were created by the discharge of a Leyden jar. The other coil had one terminal connected to the filament of a lamp, and the collecting plate to one terminal of a galvanometer, the second terminal of the latter being connected to the second terminal of the coil. I found, to my delight, that my anticipations were correct, and that electric oscillations created in the second coil by induction from the first were rectified or converted into unidirectional gushes of electricity which acted upon and deflected the galvanometer.

I therefore named such a lamp with collecting metal plate used for the above purpose an *oscillation valve*, because it acts towards electric currents as a valve in a water-pipe acts towards a current of water. I soon found that for the purposes of wireless telegraphy quite a small low-voltage lamp with a metal cylinder placed round a carbon or metal loop filament was a very effective rectifier, and could be used for converting the feeble alternating currents in a wireless receiving aerial into unidirectional currents capable of affecting a telephone or galvanometer. It was almost immediately adopted in practical wireless telegraphy as a simple and easily managed detector, and the intermittent rectified currents were passed through a telephone. Some time after the introduction of this oscillation valve I found that another

method of employing it as a detector was as follows:

If we connect the plate of the valve with the negative terminal of the filament-heating battery, and insert in that circuit a battery for creating a thermionic current, we can delineate a characteristic curve, as already described, by varying the E.M.F. of the plate circuit battery. That curve has generally some places in it at which the slope changes rather quickly. If we adjust the E.M.F. of the plate battery to work at that point, and then by means of a transformer superimpose a feeble oscillatory E.M.F. derived from a wireless receiving aerial, the thermionic current will oscillate from one value to another, and it is easy to see from the concave form of the characteristic curve that the mean value of this varying thermionic current is greater than the value of the steady thermionic current when the oscillations are not superimposed on the steady or battery voltage. This mode of usage in the case of valves with a certain degree of exhaustion in the bulb gives very great sensitiveness in the detection of radio-signals. It is commonly called the potentiometer method because the extra steady voltage required in the plate circuit is derived by employing a fraction of the voltage of the battery used for incandescing the filament by means of a potentiometer resistance.

This is, perhaps, the place to refer to another view of the mode in which my valve acts even when no additional E.M.F. is placed in the plate circuit. The characteristic curve of a valve is found not to start exactly from the point of zero voltage, but from a point on the negative side about ¾ to 1 volt. This means that if the plate is connected to the negative terminal of a filament battery by a wire, there is found to be in it a small negative electric current flowing from the plate through the external circuit to the negative terminal. The reason probably is that the electrons are shot out of the filament with a certain velocity and accumulate round the plate. The result is a tendency for them to diffuse back through the external circuit, creating a feeble electron current which can be stopped only by introducing a small counter E.M.F. into that circuit. Hence the characteristic curve starts from a negative point on the voltage axis. At the place where it crosses the zero voltage point that curve is concave upwards, and hence, for the reason just explained, the introduction into the external thermionic circuit of a feeble alternating high frequency electromotive force will result in an increase in the mean or average thermionic current. Hence the valve is sensitive to feeble electric oscillations and rectifies them, not by quite suppressing all current in one direction, but because the thermionic current is greater for a given E.M.F. applied in one direction in the thermionic current than when that E.M.F. is applied in the opposite direction, whilst the mean value of the thermionic current throughout the complete cycle is greater than its value when the alternating E.M.F. is not applied.

We must now turn to consider an improvement which was introduced in 1907 into the thermionic valve, for which credit must be given to Dr. Lee de Forest. He placed a grid or zigzag of wire carried on a separate leading-in wire between the plate and the filament of my valve, and thereby made what is now called a three-electrode valve (Fig. 1).

In modern thermionic devices the grid takes the form of either a spiral wire or else a metallic gauze cylinder, which surrounds the filament without touching it, and is in turn surrounded by the plate or cylinder which does not touch the grid. This addition enables the valve to act as an amplifier of electric oscillations as follows:

Suppose we insert in the external plate circuit a battery B_2 (see Fig. 1) giving an E.M.F., say, of 100 volts, and also a current-measuring instrument A. If the battery has its positive terminal connected to the plate, the stream of electrons emitted by the filament will be drawn to the plate and give a thermionic current of three or four milliamperes if the valve is highly exhausted. This stream of electrons will reach the plate by shooting through the holes or interspaces in the mesh or spiral grid G.

Let us now suppose that we give the grid a small negative charge by a battery B_3. This will cause the electrons coming out of the filament to be partly repelled, and therefore the thermionic current in the plate circuit will be reduced perhaps even to zero. Again, let us give the grid G a small positive charge. This will attract the emitted electrons, and they will shoot through the grid with increased velocity. Therefore the thermionic current will be increased. The important point to notice is that, owing to the small electrical capacity of the grid, and also owing to the high voltage acting in the plate circuit, a very small expenditure of power on the grid circuit will vary or modulate a much larger amount of power in the plate circuit. Just as the pressure of a child's finger on the switch may start or stop an electric

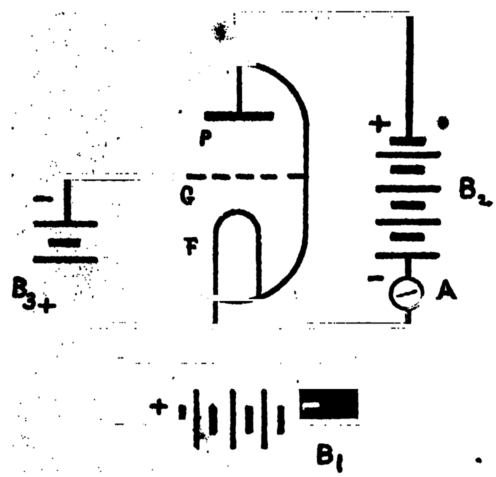

FIG. 1.—Conventional diagram of a three-electrode valve. P, a metal plate or cylinder in a highly exhausted glass bulb. G, a grid or perforated plate or spiral wire. F, the lamp filament. B_1, the filament-heating battery.

motor of several horse-power, or a feeble current passing through a telegraph relay start or stop a large current, so the three-electrode valve acts as a relay.

If we plot a curve delineating the variation of thermionic current with varying grid voltage or potential for such a three-electrode valve, we find that curve over wide limits to be nearly a straight line. This means that the change in plate current is proportional to the change in grid voltage. However rapidly the grid voltage may change, so nimble are these little electrons that the thermionic current copies on a magnified scale the changes of grid potential. Hence the arrangement is called a thermionic amplifier.

We can, however, advance further. If we cause the plate current of one valve to pass through the primary coil of a transformer, and then connect the terminals of the secondary coil of the latter respectively to the grid and filament of a second valve, we find that the fluctuations in the plate current of the first valve can be made to generate exalted potential variations of the second valve, and this again to create magnified variations of the plate current of the second valve. This mode of connection is not limited

to two valves; we can thus employ three, four, or more valves *in cascade*, as it is called, and each one multiplies or amplifies the effect of the one before. It is this use of three-electrode valves in cascade that has given us recently such vastly increased powers of detecting wireless waves. The last or final amplifying valve may be made to operate a detecting or rectifying valve, or perhaps a crystal detector.

But there is an additional very valuable power possessed by the thermionic valve, viz. that it can generate electric oscillations as well as detect them. We have already seen that the fundamental property of this valve is that variations of grid potential create similar variations of plate or thermionic current. Supposing, then, that this latter current is passed through a coil over which is wound another secondary coil connecting the grid and filament (Fig. 2). It is possible so to make the connections that any increase in the plate current will give the grid a negative charge and so immediately reduce the plate current. Conversely, any reduction of plate current will give the grid a positive charge which will again increase the plate current. Hence the operations in the plate current when once started will be maintained, the energy required being drawn from the battery B (see Fig 2) in the plate circuit. The action

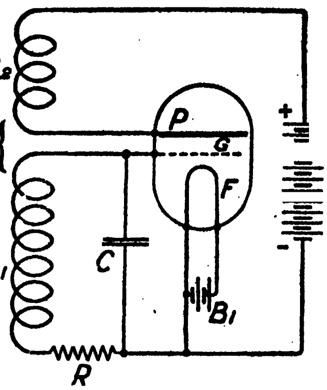

FIG. 2.—Connections for generator valve.

resembles that in the well-known experiment called the singing telephone.

The discovery of the oscillation-producing power of the valve was of great importance, because it at once put it in our power to conduct wireless telephony with simple, easily managed apparatus. The principles of radio-telephony are briefly as follows: At the transmitting station we have to establish in the sending aerial undamped or persistent oscillations and to radiate continuous waves. By means of a carbon microphone we have then to modulate the amplitude or intensity of these waves in accordance with the wave-form of the speaking voice.

The arrangements for a wireless telephone transmitter are, then, as follows: By means of a thermionic valve, with its plate and grid circuit inductively coupled, we set up, as already explained, persistent electric oscillations in the plate circuit, and these are transferred by induction to an aerial wire properly tuned to sympathetic vibration. High frequency electric currents, therefore, flow up and down the aerial. These produce magnetic and electric effects in surrounding space which are propagated outwards as an electromagnetic wave. We have in the next place to vary the amplitude of these radiated electromagnetic waves by a speaking microphone, and this is done by means of a control valve. This latter valve has its grid circuit inductively connected by a transformer with a circuit containing a battery and a telephone transmitter.

Hence, when speech is made to the mouthpiece of the carbon microphone, this varies the electric current through it, and therefore the potential of the grid, in accordance with the wave-form of the speech sound. The plate circuit of this control valve is joined in parallel with that of the generating or power valve, and the result is that speaking to the carbon transmitter modulates the amplitude of the aerial current, and therefore the amplitude of the radiated waves, in accordance with the speech wave-form.

At the receiving station these electromagnetic waves impinge on the receiving aerial and create in it very feeble alternating currents, which are a copy on a reduced scale of those in the transmitting aerial. These are then amplified by valves in cascade, rectified, and sent through a Bell receiving telephone. The result is that the latter emits sounds which closely imitate the speech sounds made to the distant transmitter. We require very high E.M.F. to create a thermionic current of sufficient strength for wireless telephony. This is now obtained by rectifying a high-voltage low-frequency alternating current by a Fleming two-electrode valve.

The whole of the appliances are usually contained in a small cabinet. A ½-kw. radio-telephone set as made by the Marconi Co. will work over 200 miles and transmit speech perfectly. More powerful arrangements on the same principle have telephoned from Chelmsford to Rome.

For aircraft radio-telephony it is usual to provide a small high-tension dynamo driven by a wind-screw to give the requisite direct high plate voltage. The filament-heating currents are provided from small closed storage cells. The aerial wire is a long trailing wire about 250 ft. in length, which is unwound when required from a drum. The actual valve apparatus may be placed at any convenient place in the aeroplane body and yet be controlled by the pilot or observer from his seat. The mere act of taking hold of the microphone transmitter closes a switch which lights up the valves and throws over the aerial wire into connection with the transmitting valve. Such aircraft radio-telephones will operate over a distance of fifty miles or more. So sensitive are these cascaded valve detectors that it is not even necessary to use a long aerial wire at all. A very few turns of insulated wire wound on a wooden frame, called a frame aerial, connected to the receiver suffice to collect and detect the electric wave signals.

Experiments were conducted in March, 1919, by the Marconi Co. to ascertain the minimum power required to transmit by these valve generators articulate speech across the Atlantic during daylight hours. The transmitting plant consisted of two three-electrode generating valves, with a third control valve for speech modulation. A small alternator of 2·5 kw. power supplied an alternating current which was stepped up in potential to 12,000 volts and rectified by a two-electrode or Fleming valve. The reception was by a series of six valves in cascade, with a final detector valve. The speech transmission was perfectly good and clear across the Atlantic, and so loud at Chelmsford, five hundred miles away from Ballybunnion, Co. Kerry, that it could be heard on a simple frame aerial.

Before leaving the subject of radio-telephony it may be remarked that, both in connection with it and with the everyday uses of radio-telegraphy in maritime intercommunication, there is a great demand for an effective wireless call-bell. I have recently devised a form of call-bell which depends upon the use of a new type of four-electrode valve made as follows: A highly

exhausted glass bulb contains a straight filament of tungsten, which is rendered incandescent by a 6-volt battery. Around the filament are arranged four narrow curved metal plates having their curved sides facing the filament and very near to it. Each of these plates is carried on a wire sealed through the glass bulb. The plates are arranged round the filament, as shown in Fig. 3.

Two of these plates on opposite sides of the filament, viz. 3 and 4 (see Fig. 3), are called the potential plates, and the other two the collecting plates. The collecting plates are joined together outside the bulb and connected to the positive terminal of the filament-heating battery, and a galvanometer G or telegraphic relay is inserted in that circuit. The electronic emission from the filament then creates a current which flows through the galvanometer or the relay, as in the Edison experiment. If the two other plates have a small potential difference made between them, either of constant direction or else a high-frequency alternating difference, this suddenly reduces the thermionic current. The potential difference of the potential plates introduces a new electric force into the field which deflects away the electrons proceeding from the filament and prevents them from reaching the collecting

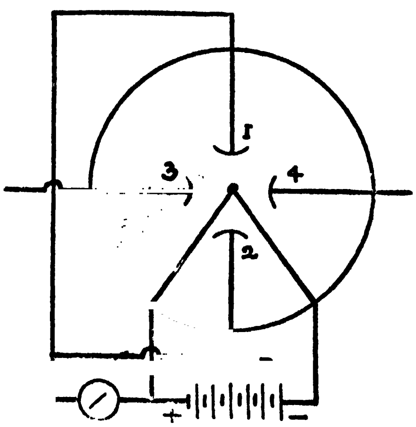

FIG. 3.—Fleming four-anode valve. 1 and 2 are the collecting plates. 3 and 4 are the potential or deflecting plates. B is the filament-heating battery, and the central dot is the end-on view of the straight filament. G is a relay or galvanometer.

plate. If, then, we connect the potential plates to the ends of a resistance of about 15,000 or 20,000 ohms, and include this resistance in the plate circuit of an ordinary three-electrode valve, the thermionic current of the latter flowing through the resistance will create a terminal potential difference which arrests the thermionic current of my new valve. Hence the relay does not operate. If, however, we give an extremely small negative potential to the grid of the three-electrode valve, then this reduces the thermionic current of the latter and increases that of the other valve, which again in turn causes the relay to close contact, and it may be caused thereby to ring a bell. The negative grid potential can be derived from the oscillations in an aerial wire as above described. In this manner I have constructed an arrangement by which the ordinary feeble antenna oscillations can be employed to ring a call-bell. The operator can then switch over the aerial to an ordinary valve receiving set and listen to the telephone.

It remains to say a few words on the methods by which the thermionic valve is employed in the reception of signals made by undamped or continuous waves. By far the best method of receiving signals by these waves is by the so-called beat-reception. If two sets of waves of slightly different wave-length are superimposed, no matter what sort of waves they may be, the result is to produce a compound wave with periodically increasing and decreasing amplitude. These augmentations are called the *beats*.

If a continuous electric wave falls on an aerial it creates on it continuous oscillations. Suppose, then, that we generate also by some local means in the aerial wire undamped oscillations differing in frequency, say by 1000, from the incident waves. The result will be to produce in the aerial electrical beats having a frequency of 1000. These act to a receiver just as do damped trains of waves with a train frequency of 1000. They can be rectified and detected by a valve and telephone, as already explained. It is now quite easy to produce high-frequency oscillations of any required periodicity by coupling a three-electrode valve to the aerial and then coupling the grid and plate circuits of the valve. Sometimes a separate three-electrode valve is used to rectify and detect the beats. Capt. H. J. Round has, however, invented ingenious methods by which one and the same thermionic valve can be used simultaneously to generate and to detect the beats.

We must, in the last place, glance at the uses of the thermionic valve in connection with ordinary telephony with wires. When the rapidly fluctuating electric currents which are propagated when a speaker at one end of a long line converses by telephone with an auditor at the other flow along a copper telephone line, two effects take place which militate against clear and audible speech transmission. First, the current generally is enfeebled as it flows, and this is called the attenuation. Secondly, the different harmonic constituent currents which go to make up the complex wave-form which corresponds to each articulate sound are differently enfeebled.

The vibrations of high pitch are more enfeebled than those of lower pitch. The first effect reduces the loudness of the speech received, and the second its articulate clearness or quality. The cause of the general enfeeblement is the resistance of the line, which fritters away the energy of the speech electric currents. Until lately the only known method of overcoming it was by putting sufficient copper into the line, but this, of course, means cost.

The thermionic valve is, however, able to make a very large economy in copper. It has already been explained that the three-electrode valve can act as an amplifier. Suppose, then, that we cut a long telephone line in the middle and insert on one side a transformer, the secondary terminals of which are connected to the grid and filament of a valve, whilst the plate circuit also contains a battery and a transformer of which the secondary circuit is in connection with the continuation of the line. Feeble telephonic currents arriving at the valve would vary the potential of the grid, and this, as just explained, would fluctuate in like manner, but with increased energy, the plate current. The transformer in the plate circuit would then re-transmit the speech current, but with exalted amplitude. The valve can thus be used to counteract the effect of resistance on the line. In practice, however, the arrangements are a little more complicated, because a telephone line has to be used in both directions.

If our trunk telephone line system in Great Britain had to be laid over again, it is perfectly certain that a very great economy in copper could be made by a widespread use of the thermionic valve as a repeater and relay. It repeats so perfectly that we may certainly say it has completely outclassed all previously invented forms of microphonic relay. . . . .

Obituary.

PROF. J. C. F. GUYON.

THE death of Prof. Jean Casmir Félix Guyon, at the end of his eighty-ninth year, removes the last of three famous Paris specialists in genito-urinary surgery; of these Civiale was much the senior, whereas Albarran (1860-1912) was Guyon's brilliant pupil and succeeded him in the professorial chair so far back as 1896. Guyon, though naturally little known to the younger generation of British surgeons, ranks with the late Sir Henry Thompson (1820-1904), with whom professionally he may be compared. Both these pioneers adopted and improved the eminent American surgeon Bigelow's practice of litholapaxy, or the complete removal of all the fragments of a crushed calculus from the urinary bladder at one sitting. Guyon was recognised as a great teacher in his speciality, and for years attracted students from all parts of the world to his clinic at the Necker Hospital.

Guyon was born on July 21, 1831, at St. Denis, in the island of Réunion, and it may be mentioned as a rather curious coincidence that his famous successor, Joaquin Albarran, was also born abroad, namely, in Cuba. Guyon worked first at Nantes and then at Paris, where he was *interne* in 1854 and prosector to the faculty in 1858. His graduation thesis, on "Fibroid Tumours of the Uterus," bears the date 1860; in 1862 he became surgeon to the Paris hospitals, in 1863 *agrégé*, and professor in 1877. His two chief works, "Leçons cliniques sur les maladies des voies urinaires" (1881)—which passed into a second edition in 1885, and a third in two volumes in 1894–96—and "Leçons cliniques sur les affections chirurgicales de la vessie et de la prostate" (1886)—edited by his former resident, Dr. F. P. Guiard—embodied his teaching at the Necker Hospital, and were both translated into German and into Russian. Though famous as a genito-urinary specialist, Guyon took a broad view of surgery, adopted Lister's methods as early as 1876, and was the author of a work of 672 pages on general surgery, dealing with diagnosis and operations in general, entitled "Eléments de chirurgie clinique." Although now somewhat forgotten from his great age and the interval of almost a quarter of a century since he quitted the chair of genito-urinary surgery, Guyon received the honours due to his work and position; he was a Commander of the Legion of Honour, a member of the Institute (Academy of Sciences) and of the Academy of Medicine, and on August 3, 1900, his former pupils, of whom Lucas-Championnière was the senior, presented him with a medal executed by Bottée as a mark of their affection and admiration.

MR. ALEXANDER JAMES MONTGOMERIE BELL, who died on July 3, aged seventy-four, was a fellow of the Geological Society who devoted his leisure for many years to the study of the deposits in southern England in which palæolithic flint implements occur. His researches on the gravels and associated deposits at Wolvercote, near Oxford, were especially valuable, and were described in a paper published in the Geological Society's Journal in 1904. He regarded certain disturbed layers as "ice-drifts," and emphasised the importance of distinguishing "rainwash-drifts" from regular deposits. From an examination of the fossil remains of plants and beetles, he concluded that in late Pleistocene times the climate of the Thames valley was more continental than it is at present. It is understood that Mr. Bell left a general summary of the results of his researches in a manuscript, which we hope may be found in a form suitable for publication.

Notes.

DR. G. C. SIMPSON, F.R.S., Meteorologist to the Government of India, has been appointed Director of the Meteorological Office as successor to Sir Napier Shaw, who retires on reaching the age-limit after brilliant pioneer service. Dr. Simpson was meteorologist and physicist to the British Antarctic Expedition, 1910–13, and served on the Indian Munitions Board from 1917 to 1919. In 1905 he was appointed a Scientific Assistant in the Meteorological Office, and in 1906 joined the staff of the Indian Meteorological Department. He is the author of a number of papers of scientific importance, including one on the electricity of rain and its origin in thunderstorms, published in the Phil. Trans. in 1909. Only last year Dr. Simpson completed an elaborate discussion of the meteorological work of the British Antarctic Expedition, 1910–13. As successor to Sir Napier Shaw his appointment promises a continuation of progress along lines which will advance meteorological science and maintain the high position which the British Meteorological Office now occupies through its work in recent years.

DR. L. V. KING has been appointed Macdonald professor of physics at the Macdonald Physics Building, McGill University. The chair has been held in succession by Prof. H. L. Callendar, Sir Ernest Rutherford, Dr. H. T. Barnes, Prof. H. A. Wilson, and by the present director, Dr. A. S. Eve. Prof. King was born at Toronto, Ontario, in 1886. In 1905 he graduated B.A. at McGill University with first-class honours and gold medal in mathematics and physics. He was elected scholar of Christ's College, Cambridge, in 1906, and appointed lecturer in physics at McGill University in 1910, assistant professor in 1912, and associate professor in 1915, when he also was awarded the D.Sc. degree of McGill University. In 1915 Prof. King began investigations on sub-

marine acoustics for the Electrical and Submarine Committee of the British Board of Inventions. He has been engaged for some time on important researches on the efficiency of fog-signal machinery and on the measurement and distribution of sound.

IN an illuminating article in the *Times* of July 29 Dr. Herbert Levinstein explains the close co-operation of the German Government and the combine of the German aniline dye manufacturers known as the 'Interessen Gemeinschaft" or the "I.G.," which enabled the German General Staff to provide large quantities of high explosives and poison gases when the need arose after the Battle of the Marne. Until then the aniline dye factories had not been mobilised; they had continued their ordinary vocation of manufacturing dyes because the great accumulation of high explosives by the Germans had been expected to overwhelm the French in a short time. After the Marne, however, there was an actual shortage of munitions in Germany, and the vast resources of the dye factories were then requisitioned for the production of further quantities of high explosives and of poison gases. Whilst the varied collection of dye-making plant in Germany could be immediately adapted for this purpose, the special plant erected in this country cannot so easily be utilised in the reverse direction, and it is vitally necessary that we should possess extensive plants for the manufacture of dyes comparable with those of the "I.G.," so that not only can the necessary provision be made for any future war, but also facilities for chemical research, which, in chemical warfare and in the dye industry, can be supported only by the industry itself, may be provided to enable us to maintain a premier position.

WE have now had an opportunity of examining at the London office of Messrs. Barr and Stroud, Ltd. (15 Victoria Street, S.W.1), the latest form of that remarkable instrument devised by Dr. E. E. Fournier d'Albe and perfected by Prof. Archibald Barr by which it is possible for a blind man to read ordinary print by listening to sounds in a telephone receiver. The apparatus, which is called the optophone, was fully described by the inventor in an article in NATURE of May 6 last, where the way in which, by the use of selenium cells, a series of distinctive sounds is produced as the "eye" of the instrument passes over the letters was explained. To anyone who has not tested the instrument it is difficult to believe in the possibility of making the sound combinations sufficiently distinctive for even a trained operator, blind or otherwise, to recognise the different letters easily. A few minutes' experimenting, however, is sufficient to dispel all such doubts. After realising the principles of the action, the present writer was, in one or two cases, actually able to name correctly the simpler letters at a first attempt, and there is no doubt that a blind person could be trained to read with the apparatus more easily than he could become expert in picking up a wireless message in Morse. The way in which the letter "w," for example, is represented by beautiful little descending and ascending arpeggios sung softly in one's ear, or a single harmonious chord denotes an "i," is quite fascinating. The adjustments of the apparatus, although delicate, are not beyond the powers of a blind reader of intelligence, and we feel sure that the institutions (including St. Dunstan's and others) which have already acquired these instruments will find them appreciated by the sightless readers whom they train. We have not the space to direct further attention to the numerous little mechanical details which contribute so much to the success of the instrument. It must suffice to say that they are largely the result of long personal attention by Prof. Barr himself, who had at his disposal the unrivalled resources of the well-known firm of range-finder manufacturers.

MAJOR W. E. SIMNETT has retired from the direction and editorship of the *Technical Review* on his appointment to direct the Intelligence Branch of the Ministry of Transport.

THE Harveian oration of the Royal College of Physicians will be delivered by Sir Frederick Andrewes on St. Luke's Day, October 18; the Horace Dobell lecture by Sir William Leishman on November 2; the Bradshaw lecture by Dr. R. C. B. Wall on November 4; and the FitzPatrick lectures on the History of Medicine by Dr. E. G. Browne on November 9 and 11.

ACCORDING to a notice appearing in *La Technique Moderne* for May, a French committee is now engaged in the establishment of an institute for chemical research as applied to industry. The idea is to create, on the model of the Pasteur Institute and the large American research institutes, a powerful scientific organisation at which all kinds of researches of interest to industry may be carried out. In addition to founding the research institute at Paris, the committee intends to provide the means to make grants on a liberal scale to those workers who wish to carry out their work in private laboratories. Missions will also be sent abroad for the purpose of studying conditions there.

THE use of the different species of woods and the preference accorded to the various kinds in industry are determined mainly by experience. In France especially no methodical investigations have hitherto been carried out on the various timbers grown in the country. This want is now to be filled by the enterprise of the Administration des Eaux et Forêts. A series of researches will be undertaken by that Department in consultation with the Technical Section of the Aeronautics Department, dealing with the properties of native woods from the point of view of their utilisation. The first-named Department will collect samples of wood of known origin, and these will be subjected to suitable mechanical tests by the Aeronautics Department. The results of the tests, together with the specimens, will be sent to the research station of the Nancy Forestry School.

AN important discussion on "The Present Position of Vitamines in Clinical Medicine" was opened by Prof. F. Gowland Hopkins at the eighty-eighth annual meeting of the British Medical Association at Cambridge. A full report of the proceedings will be found in the *British Medical Journal* for July 31. Prof. Hopkins said that he deplored the scepticism

concerning the whole question of vitamines which has been displayed by certain members of the medical profession, and gave definite experimental evidence of the effects of deficient diets. The remainder of the paper was devoted to the principal forms of disease which are now recognised as associated with the absence, to a greater or less degree, of one or more of the vitamines from a dietary. The diseases mentioned were scurvy, beri-beri, the xerophthalmia of experimental animals, and rickets. During the discussion which followed further evidence of the importance of vitamines in a normal diet was given by various contributors.

WE have received from Messrs. Flatters and Garnett, Oxford Road, Manchester, a catalogue of mounted microscopical preparations which they are able to supply. The list is a very comprehensive one, ranging from numbers of protozoa, worms, insects, and other invertebrates to vertebrate tissues and structures. Botanical preparations, bacteria, diatoms, petrological specimens, and textile fibres are included, and the firm is also prepared to supply botanical material and pond-life for class purposes. The prices appear very moderate.

IN *Medical Science: Abstracts and Reviews* for July (vol. ii., No. 4) one of the reviews is devoted to the subject of diabetes, and some interesting particulars are given. In the years immediately preceding the war the deaths from diabetes remained constant, whereas during the four years 1916–19 they declined from 444 pre-war to 202. The male sex showed a greater decline than the female, and the percentage mortality among children sank as low as in adults. No case of diabetes was observed as the result of cerebral concussion. These facts give no support to the nervous hypothesis of the causation of diabetes. It is stated that there was a similar diminution in diabetes during the siege of Paris in 1870–71, and during the German occupation of Lille in the late war many of the less severe diabetic cases improved or recovered—probably as a result of the food scarcity.

A CHADWICK lecture on "Health Conditions in Eastern Europe: Typhus a Serious Menace" was given by Dr. Norman White (Medical Commissioner, Typhus Commission, League of Nations) on July 15 at the Surveyors' Institution, Westminster, S.W.1. The countries considered were Latvia, Esthonia, Lithuania, Poland, and the Ukraine. Poland, through which pass the main lines of communication with Russia, has suffered more than her smaller neighbours. Sanitary conditions in this portion of Europe are in a deplorably backward condition, and soap, fuel, and other facilities for cleanliness are unobtainable in many districts, while louse infestation among the poorer classes is almost universal. A large portion of the lecture was devoted to the consideration of typhus fever, the part played by the louse in the conveyance of the disease being described. Emphasis was laid on the danger to other countries arising from the persistence of this focus of epidemic disease. The essential requirements for the anti-typhus campaign were outlined, and the point was made that every country in the world has a very real concern in the existing health conditions of Eastern Europe, apart from humanitarian considerations.

DR. W. CROOKE in the Journal of the Royal Anthropological Institute (vol. xlix., July–December, 1919) discusses the question of "Nudity in India in Custom and Ritual." The present Hindus, like all Orientals, wear scanty clothing, but the rules of decency are generally observed. There are, or were until recently, several degrees of habitual nudity. The earliest stage of clothing seems to have been that of bark, and this and drapery made of sedge and other leaves are still in use in parts of the country. Nudity appears in various magical rites like rain-making, while in the case of some ascetics it implies the renunciation of all family and social obligations. This condition, in the case of rites connected with magic and witchcraft, is fully illustrated, as well as the ætiological legends which have been invented to explain the custom.

IN the Journal of the Royal Anthropological Institute (vol. xlix., July–December, 1919) Mr. Harold Peake discusses "The Finnic Question and some Baltic Problems." Until recent years it was generally supposed that the Finns, like the Lapps and Samoyeds, were an Asiatic people with Mongoloid affinities. On the other hand, Ripley supposes the Finns to be of the Nordic race or closely allied to them, while Ruggeri believes that Proto-Nordics, Proto-Finns, and Proto-Mediterraneans are branches of a common stock which originated on the confines of Europe and Asia. Mr. Peake's conclusion, after a careful review of the evidence from physical anthropology and culture, seems to be that towards the latter half of the third millennium a period of drought occurred in the steppe-lands of the northern hemisphere and caused the Nordic steppe-folk to disperse in various directions. It may be that to this date we must attribute the retreat to the Volga basin which resulted in the hybrid type known as the Red Finns, but the main body seems to have crossed or passed round the plain of North Germany to Denmark, where, perhaps, they met and coalesced with the people of the kitchen-middens; they afterwards passed across the Danish islands to Sweden as the men of the passage-graves, driving before them the Mongoloid aborigines, who had now reached the stage of Arctic culture.

THE lighting of picture-galleries and museums presents problems that have not yet been solved in practice, and especially is this the case with reflections from glass. In the July issue of the *Museums Journal* Mr. Hurst Seager sets forth the scientific principles that are necessary for success. At the recent conference of the Museums Association he gave a brilliant demonstration of their application, and an account of this appears in the August number of the journal. All museum directors should study Mr. Seager's advice, of which the correctness has been proved by a gallery at Wanganui, N.Z. With the July number the *Museums Journal* opened a new volume; with the August number its price is raised to 2*s*.

We have received from the British Association Committee on Zoological Bibliography and Publication recommendations as to the way in which an author should introduce references to previous work quoted by him. Footnotes are condemned. The committee recommends that, at all events in the case of longer articles containing many references, a "list of works referred to," arranged with the names of authors in alphabetical order, should be printed at the beginning or end of each article. In these lists the title of the paper, name of the journal, date, number of series and volume and the pages should be given. It would then, in the text of the article, be necessary to quote only the author's name and the date, with the addition of a page-number where required. The committee also discusses additions to the rules which should be followed when introducing new genera or species in zoological publications.

In the Report of the American Museum of Natural History for 1919 President H. F. Osborn continues his vigorous beating of the educational drum. The museum, he writes, "is actually going backward." Want of space and want of funds prevent the orderly arrangement of the material already accumulated. When the dinosaur rubs shoulders with the mammoth, small wonder that newspaper science represents them as contemporaries. The harmonious development of exhibition galleries is at a standstill. African, Asiatic, Polar, and Oceanic Halls are lacking; for lack of halls of fishes, of reptiles, and of birds of the eastern hemisphere these animals are untruthfully arranged. And the remedy? Extension of the museum on the plan originally intended, partly as a memorial to Theodore Roosevelt, whose connection with zoology is a great asset for more than one museum, and partly by separating the tax rolls and assessments for educational purposes from the general municipal rates and starting a direct poll-tax for education—a tax which would have a basis ten times as broad and would be more willingly paid. It must not be inferred that Dr. Osborn overlooks the research work of the museum, which is the necessary foundation of its educational activities. The team-work on fossil vertebrates accomplished under his guidance by Dr. W. D. Matthew and an accomplished staff is a brilliant witness to the contrary, and the report records a long list of researches and publications in various branches of science. But in New York, as in this country, it is through an appeal to the public on educational grounds that funds can most readily be raised.

Science and Industry for March, the official journal of the Australian Institute of Science and Industry, contains a detailed account of the results of investigations in New South Wales on the extraction of tannins from wattle-bark, which are of great importance to the Australian leather industry. For many years the bark used has been obtained from two species, the golden wattle of South Australia (*Acacia pycnantha*) and the black or green wattle (*A. decurrens*) and its varieties. As a result of the gradual destruction of wattle-trees the Australian supply has been largely supplemented by wattle-bark imported from Natal, where plantations grown from Australian seed have been formed. A valuable tan-bark is also yielded by the mallet (*Eucalyptus occidentalis*) of Western Australia. The faulty methods adopted for the extraction of tannins are criticised, and an improved process is suggested.

In his presidential address to the Linnean Society of New South Wales (abstract of Proceedings, March 31, 1920) Mr. J. J. Fletcher referred to the morphology of the so-called phyllodes characteristic of many of the Australian acacias. According to the definition in text-books, these are the flattened leaf-stalks of bipinnate leaves which have lost their blades, whereas they really represent the primary axes of bipinnate leaves which have lost their pinnæ. Accordingly the name "euphyllode," as implying something more than merely flattened petioles, is proposed for them. The president also referred to the recent costly visitation of drought, and pointed out the need for a handbook or manual setting forth the theoretical complementary side of the practical activities of the man on the land, especially in relation to drought problems. A synopsis indicating the scope and contents of such a handbook was offered for discussion.

Mr. F. Debenham, who accompanied Capt. Scott on his last Antarctic expedition, puts forward (Quart. Journ. Geol. Soc., vol. lxxv., p. 51, 1920) an ingenious suggestion to explain the transfer of marine deposits from the sea-floor to the surface of glacier ice, and so finally to the land when glaciers melt away. A massive glacier protruding seaward may pick up such material by accreting ice along its base. Successive accretions from the freezing sea raise this lower layer until finally it comes to the surface, where ablation is active during summer. It may then be transported to some point impinged on by the ice. The interesting occurrence of sodium sulphate, as mirabilite, in the ice is held to be due to concentration of sea-water in cold sub-glacial lagoons, the water of which has furnished ice, enclosing the separated salt. The case of the Great Salt Lake of Utah, in which sodium sulphate separates when the temperature falls below about 20° F. (−7° C.), is cited as an illustration.

A memorandum regarding the probable amount of monsoon rainfall in 1920 by Dr. Gilbert T. Walker has recently been issued. Data of importance are given showing how the monsoon rainfall in India is affected by previous weather conditions over various parts of the earth. In summing up the effects of the various factors it is mentioned that the prejudicial effect of snowfall from Persia to the Himalayas is exerted when at the beginning of June the accumulations extend over a larger area than usual. The great excess of snow reported this year is confirmed by the low temperatures in the Punjab. Heavy rainfall in South Ceylon, Zanzibar, East Africa, and Seychelles is prejudicial, but data for this year show a moderate deficit or normal conditions. A close relationship exists between heavy rain in Java from October to March and low barometric pressure in Bombay in the succeeding six months; in Java the rainfall was nearly normal and its effect is negligible. High barometric pressure in Argentina and Chile is

a favourable condition, but this year pressure is in slight defect. It is stated that the conditions indicate that in North-West India the monsoon is likely to be weak, at any rate in the earlier part of the season, and for the rainfall of the Peninsula, North-East India, and Burma the indications are not sufficiently definite to justify a forecast.

THE Italian Laboratory of Practical Optics and Mechanics of Precision, which was founded in Florence last year on the suggestion of the Minister of Public Instruction to spread a knowledge of recent advances in instrument-making amongst those engaged in the industry in the country, has undertaken the issue of a monthly *Review of Optics and Mechanics of Precision*. The number for March and April consists of a little more than thirty quarto pages. The first seven are devoted to a continuation of a report by Prof. L. Silberstein on the quantum theory of spectra. The improvements which Sommerfeld has introduced into the theory by ascribing two degrees of freedom to the electron instead of the one degree of Bohr's theory are dealt with. Constructional optics is represented by articles on the calculation of achromatic objectives and on objectives for aerial photography. Metrology gets an article of sixteen pages on measurements of precision in the mechanics workshop by Mr. V. I. N. Williams, of Armstrong, Whitworth's, Manchester. There appears to be no publication in English which serves the same purpose for our own industries that this review does for those of Italy.

THE July issue of *Science Progress* contains a *résumé* by Mr. S. C. Bradford of the theory of the constitution of the atom propounded by Langmuir in the June issue of the Journal of the American Chemical Society last year. Unlike the "sun and planets" theory which has been so successfully developed by Bohr, the new theory assumes the electrons which surround the positive nucleus to be at rest. They form shells around the nucleus, the number in each shell being twice the square of the number of the shell counted from the nucleus. When the number of electrons is insufficient to fill a number of shells, it is the outer shell which is incomplete. In these outer shells there is a tendency for the electrons to form groups of eight or "octets" either amongst themselves or by association with the electrons of other atoms. The chemical properties of the atom depend mainly on the number of electrons in the outer shell not associated together in octets. The properties of hydrogen, helium, neon, lithium, carbon, nitrogen, oxygen, and fluorine, the similarity in the behaviour of CO_2, and N_2O, of CO and N_2, and the difficulties which compounds of nitrogen raise on the usual theory of valency, are all explained in a simple way by the new theory.

IN NATURE of July 8 we gave an account of the work done recently at the National Physical Laboratory. The appearance of the report of the laboratory for the year 1919 enables us to supplement that account by some information as to the progress of the institution as a Government establishment. With regard to buildings, the new control appears to involve exceptional delay. Extensions contemplated in 1918 and urgently needed have been approved by the Research Department, but not yet authorised by the Treasury. In consequence, apparatus already delivered cannot be housed and utilised. The number of posts in each grade of staff has been fixed, and the conditions of service approximate to those in the Civil Service. In special cases, however, promotion by length of service may be departed from, subject to the approval of the Research Department. Industry appears to be claiming many of the staff who have by their past work added materially to the reputation of the Laboratory, and it is of the utmost importance that the most promising of the younger members of the staff should be retained by sufficiently attractive posts. The Research Department has decided that commercial testing is not in future to be a function of the Laboratory.

A REPORT by Prof. J. C. McLennan on sources of helium in the British Empire has recently been issued by the Department of Mines, Canada (Bulletin No. 31). An investigation of the helium content of natural gas supplies was undertaken at the request of the Board of Invention and Research (London) in 1915, and the report embodies the results, which are now published by permission of the Admiralty. It appears that certain natural gases in Canada form the largest source of supply of helium at present known within the Empire. The percentage of helium present was found to range from zero in gases from the Toronto and British Columbia regions up to about 0·33 per cent. in gases from the Blackheath (Ontario) and Bow Island (Alberta) areas. Two methods were used for isolating the helium: (1) Combustion of the gas with oxygen, the resulting water and carbon dioxide being removed by suitable reagents, and the nitrogen and remaining traces of other gases by means of coconut charcoal cooled in liquid air; and (2) condensation of the hydrocarbons and other constituents having higher boiling points than helium in a condenser immersed in liquid air, the residue being then purified by means of charcoal as before. Figures of the apparatus employed are given. Methods based upon these processes are indicated for the large-scale manufacture of helium, and it is considered that commercial production of the gas is almost certain to be undertaken.

FROM the Central Scientific Co., Chicago, we have received a copy of its catalogue of apparatus used in chemical, bacteriological, biological, industrial, and soil-testing laboratories. The catalogue is very complete, and it indicates the thorough manner in which American manufacturers have developed the production of scientific apparatus. Practically all the articles described are stated to be "American made," the only important item of foreign manufacture being English (Whatman) filter-paper. Among other matters of interest we note the new "chain" analytical balance, in which the use of a rider and small weights is dispensed with. The finer weighings are obtained by varying the length of a small gold chain attached at one end to the beam of the balance, and at the other to a vernier which slides on a graduated vertical

column, and is operated by a milled head outside the balance-case. It is claimed that in this way the rapidity and accuracy of weighing are much increased.

AMONG the papers read at the annual meeting of the British Pharmaceutical Conference recently held in Liverpool was one by Messrs. Bernard F. Howard and Oliver Chick upon "Some Recent Samples of 'Grey' Cinchona Bark." A "parcel" consisting of 138 bales of South American cinchona bark received in March, 1920, and analysed by the authors, was found to contain 6·302 per cent. of total alkaloid, the bulk being cinchonine, the figure for which was 5·49 per cent. The bark contained only 0·027 per cent. of quinine. Mr. E. M. Holmes, curator of the Pharmaceutical Society's Museum, has examined the bark, and has expressed the opinion that it is the product of one, or possibly more forms of *Cinchona peruviana*, Howard. The large percentage of cinchonine found in the bark is probably due to the elevation at which the trees grow, as this factor, and the accompanying differences of heat and moisture, are known to influence the character of the alkaloids present.

AT the recent annual meeting of the British Pharmaceutical Conference a paper entitled "Cresineol" was contributed by Mr. T. Tusting Cocking, who showed that when oil of eucalyptus and ortho-cresol are mixed heat is evolved, and on cooling a mass of glistening crystals, consisting of an equimolecular combination of cineole and ortho-cresol, is formed. This is a new compound, which has been named "cresineol." It may be recrystallised from various solvents, and forms beautiful white, transparent, prismatic crystals, melting at 55·2° C. and boiling at 185° C. Cresineol is volatile, and possesses a pleasant camphoraceous odour. It is not caustic in its action on the skin, and yet contains 41 per cent. of cresol. Having high germicidal properties, it is likely to prove of great value as an antiseptic for both internal and external application. The fact that a solid compound is formed when oil of eucalyptus and ortho-cresol are mixed can be made use of as a means of determining the amount of cineole in oil of eucalyptus. The method is based on the determination of the freezing point of a mixture of the oil with ortho-cresol; having observed this point, one may read off directly from a curve given by the author the percentage of cineole contained in the oil.

MESSRS. W. HEFFER AND SONS, LTD., Cambridge, have in the press a book by Dr. A. Harker entitled "Notes on Geological Map Reading," the object of which is to teach the student to visualise a geological map as in three dimensions, and to show that the questions which present themselves to the field-geologist reduce to exercises in very elementary geometry. This simplicity is gained by reckoning all slopes and dips as gradients, thus enabling trigonometry and the protractor to be dispensed with. The amount of dip, the thickness of a formation, the throw of a fault, etc., are measured directly upon a contoured geological map by the use of the scale alone.

Our Astronomical Column.

THE HILL OBSERVATORY, SIDMOUTH.—The council of this observatory has just issued its annual report for the year ending June, 1920, and it is satisfactory to note that all instruments and other equipment are in good condition and that the observatory is now in full working order again. The chief work undertaken consists in photographing the spectra of stars down to magnitude 5·30 and classifying them according to Sir Norman Lockyer's scheme of increasing and decreasing temperatures. Spectra are also photographed of nebulæ and other special objects. An interesting addition has recently been made to the regular work of the observatory in the form of a line of investigation suggested by Prof. W. S. Adams. Prof. Adams has found that the relative intensities of certain lines in stellar spectra vary with the absolute magnitude of the star, and thus, provided the apparent magnitudes are known, a fairly simple method is available for the determination of stellar parallaxes. The line intensities referred to are measured by means of a wedge of dark glass specially made for the purpose, the position of the wedge being noted at which the lines are just obliterated. Some encouraging results have been obtained from preliminary work. A party of members of the British Association visited the observatory at the close of the Bournemouth meeting. The party included several eminent astronomers, some of whom have consented to form a research committee, intended to act as an advisory body on all matters connected with the research work of the observatory.

THE INFRA-RED ARC SPECTRA OF SEVEN ELEMENTS.—No. 372 of the Scientific Papers of the U.S. Bureau of Standards gives the results of an investigation on the wave-lengths longer than 5500 Å. in the arc spectra of seven elements made by Messrs. C. C. Kiess and W. F. Meggers. The yellow, red, and infra-red regions of the arc spectrum of titanium, vanadium, chromium, manganese, molybdenum, tungsten, and uranium were photographed with a large concave grating spectrograph. The photographs were made on plates sensitised to these spectral regions by means of pinacyanol and dicyanin dyes. The wave-lengths of more than 2500 spectral lines were measured, extending from the green at 5500 Å. into the infra-red beyond 9700 Å. So far as is known, impurity lines and spurious lines have been eliminated from the wave-length tables. Frequency differences which were suspected of being constant have been found in each of the spectra. Those who are specially interested in this work may obtain a copy of the paper by applying to the Bureau of Standards, Washington.

NEW SOLAR RADIATION STATION IN ARIZONA.—An anonymous benefactor has given funds to the Smithsonian Institution for the establishment of a new solar observing station in the Haqua Hala mountains in the Arizona desert. The site was chosen as "being probably the most consistently cloudless region in the United States." Dr. C. G. Abbot has gone to set up this station, which will duplicate the work that has been done for some years at Calama, Chile; it is stated that the results obtained there are of assistance in predicting the weather and temperature in Argentina. As is well known, Dr. Abbot considers that, besides the 11-year variation, there are irregular changes in the solar radiation from day to day amounting to as much as 5 per cent., which he suggests may be due either to alterations in the circulation in the sun and consequent variation in the amount of hotter matter brought from the interior, or to changes in the transparency of the solar envelopes.

Iron-depositing Bacteria.[1]

THE appeal of the monograph before us, which is one of the Professional Papers issued under the ægis of the United States Geological Survey, will probably be of direct interest only to a comparatively small section of scientific workers. Although there is much to attract the general reader, it is obvious that the work was not initiated with this end in view. It is worthy of note and a sign of the times that the data supplied by the bacteriologists should be used as a serious weapon of offence in attacking a geological problem.

Many changes, due to biological influences, take place on the earth's surface which profoundly modify the constitution of the material which is destined to become the geological strata of the future. A study of these changes will obviously throw light on the causes which have operated in the past to bring the earth's crust into being. We find in Mr. Harder's paper by far the most comprehensive treatment which we have yet seen of the activities of bacteria in effecting chemical changes in various iron compounds which come within the scope of their influence. He has undertaken the task of bringing together in the form of a critical survey the salient facts of our knowledge of the iron bacteria. This subject occupies the first half of the monograph, and is treated by the author with a masterly regard for essentials, and in it is included the results of some of his own observations and experiments on these interesting micro-organisms. It is interesting to note that the same iron bacteria are found in America as in Europe, although there are slight differences in their distribution and numbers. Thus *Spirophyllum ferrugineum* appears to possess a wider distribution than is the case in this country.

In the preface, which is written by Mr. F. L. Ransome, especial attention is directed to the results of Mr. Harder's inquiry into the physiology of the iron bacteria. Hitherto each investigator has assumed that the results claimed by him as a result of his research on the physiology of some particular species held good for all the iron bacteria. Mr. Harder, however, concludes that there are three principal groups of iron-depositing bacteria: (1) A group the members of which precipitate ferric hydroxide from solutions of ferrous bicarbonate. (2) A second group of iron bacteria that does not require ferrous bicarbonate for its vital processes. (3) A third group that attacks iron salts of organic acids, using the organic acid radicles as food and leaving ferric hydroxide, or basic ferric salts that gradually change to ferric hydroxide. We must confess to a scepticism as to the existence of such deep-seated differences among these organisms, and incline to the opinion that the phenomenon of iron-deposition on micro-organisms shows the working of a simple physiological law which operates on all in the same manner. In support we would advance the fact that Spirophyllum and Leptothrix are so closely allied that some have regarded them as pleiomorphic varieties of one and the same organism. They live in the same waters, they reproduce alike, and are in every way similar except in external form; and yet Spirophyllum is stated to be an example of the first group, whilst Leptothrix is relegated to the second group. A more cogent ground for scepticism lies in the fact that other organisms, including some of the algæ and the protozoa, possess the same attraction for iron compounds. Possibly a closer investigation of the *chemico-irritability* of micro-organisms will throw some light on the question.

[1] "Iron depositing Bacteria and their Geologic Relations." By Edmund C. Harder. United States Geological Survey. Professional Paper 113.

We can recommend the second half of the monograph to all who wish concise information from an authoritative source of the iron deposits of the world and of the factors which influence the formation and determine the mode of deposition of the iron precipitations that are taking place at the present day. With one exception iron is the most abundant element in the earth's crust. Iron salts are being constantly decomposed, and the genesis of the active agents which bring about their decomposition is given in detail. A consideration of these agents brings home to us the necessity of studying the life-histories of various micro-organisms in order to understand how the present deposits came into being. To give one example. The most important of the iron deposits is ferric hydroxide, and a study of the conditions of its formation centres largely round the fact that ferrous compounds are soluble in water containing CO_2 in excess. Now, in particular, ferrous bicarbonate percolates upwards in solution, and when it reaches the surface becomes subject to the interplay of forces, both chemical and biological, which determine its subsequent fate. We must refer the reader to the work itself for more precise information regarding the manner in which this fate is determined.

We are also given a very complete account of the various types of ferruginous sedimentary ores, and in each case the intervention of biological agencies, either in the primary or in the secondary *rôle*, as factors in the determination of the final deposition is explained in a comprehensive and accurate manner. Of greatest interest of all is, we consider, the examination of the conditions which determine the formation of bog-iron ore. These are undoubtedly mainly of a biological nature, and deserve more consideration than they have hitherto received. The interest in this ore is enhanced on account of its formation being a possible stepping-stone to the development of limanites and hæmatites, although Mr. Harder himself has not raised the point. In his reference to the ferrous carbonate deposits he does well to speak with reticence of the factors which have brought about their formation; enough evidence, however, is advanced to give pause to those who would eliminate altogether the activities of micro-organisms from the list of active agents which have brought these deposits into being. Again, Mr. Harder makes out a clear case for the intervention of micro-organisms in the formation of some, at any rate, of the iron sulphide deposits. Sulphuretted hydrogen is evolved as a result of the decomposition of animal and vegetable matter by the saprophytic bacteria. The formation of sulphides with iron compounds is the next step, and it is of great interest that we see the process at work at the present day in the development of the "blue mud" of the ocean bottom.

Both biologists and geologists will be grateful to Mr. Harder for the work which he has done in the preparation of this monograph. DAVID ELLIS.

The Association of Technical Institutions.

THE Association of Technical Institutions opened its summer meeting at the University of Cambridge on July 23, with the Marquess of Crewe, the president, in the chair. The meeting was extended over the following day, when the chairman of the council, Mr. Dan Irving, M.P., presided. Papers were submitted on "A National System of Education," by Principal J. C. M. Garnett (Manchester); on "The Necessity for Close Co-operation between Technical Colleges and the Universities," by Principal C. Coles (Cardiff); on "Continuation

Schools and their Relation to Technical Institutes and Colleges," by Principal C. L. Eclair-Heath (Newcastle-upon-Tyne); and on "Local Colleges and Adult Education," by Principal L. Small (Bootle).

The suggestions of Mr. Garnett for the establishment of a national system of education in England during the next ten years are embodied in a pamphlet presented to a meeting of the newly formed Federal Council of Lancashire and Cheshire Teachers' Associations in January last. It is accompanied by an elaborate "flow" diagram showing graphically in colour the various types of scholastic institutions suggested, of which as many as sixteen are depicted, ranging from the elementary school upwards to the university, and dealing with school and university life up to the twenty-fifth year. It is declared that "it is the main business of all education to form in the mind of every person a single wide interest centred in a supreme purpose," and that "it is the subordinate business of education to train young people so that they shall be able to realise their central purpose in some particular form of service to their fellows. For example, the particular form of service for which technical and commercial education prepares is that of providing the material wealth without which no community—so different in this respect from an individual—can make much progress towards the fulfilment of high spiritual purposes." The pamphlet proceeds to divide those who are to occupy the various positions in industry, commerce, and other departments of national life into four classes: Leaders in thought and action, about 3 per cent.; skilled managers and assistants, about 17 per cent.; skilled wage-earners, about 40 per cent.; and unskilled labourers and repetition workers, about 40 per cent.

The scheme suggested received the attention of a meeting, held in June last, of the headmasters of secondary schools in Lancashire, Cheshire, Cumberland, and Westmorland, who expressed strong disapproval of its proposals, which they thought too mechanical, and of the suggestion that there should be lower and higher secondary schools. They were not persuaded that it was desirable to prevent the individual growth and development of each school, and that whilst transference and change of grade seemed to be its keynote, the headmasters believed in elasticity, growth, and continuous development.

The purpose of Mr. Coles's paper is to set forth the present unsatisfactory position of technical institutions in this country, and to propose remedies therefor in respect alike of the development of higher education in technical institutions and of the administration thereof, so as to bring them into closer relation with the work of the universities. Mr. Coles advocates the institution of faculties of technology and commerce in connection therewith, and suggests that an investigation should be set up, as in 1882, into the condition of higher technological education in the United Kingdom.

Mr. Small's paper, accompanied by notes by Principal J. F. Hudson (Huddersfield), deals with local colleges and adult education. The authors advocate the development of the technical institute into "the local college," an official term appearing for the first time in the revised regulations for continuation, technical, and art courses issued by the Board of Education in February, 1917, so that it shall include not only the training of workers in commerce and in specific industries, but also their continued education as citizens by the introduction of humanistic studies, and to provide generally for non-vocational subjects of a literary, scientific, and recreative character, together with facilities for the study by adult workers of questions calculated to promote a better understanding of the character and problems of social life. Already with this end in view the Huddersfield Technical College has entered into close relations with the Yorkshire District Council of the Workers' Educational Association.

Mr. Eclair-Heath in his paper declares that the idea of continuation schools is not new, and instances the excellent example of the Royal Dockyard Schools at Deptford and elsewhere. He says that early vocational education is undesirable, and that the schools should be held apart from works. He favours mixed schools and the introduction of religious instruction, and suggests that there should be set up a system of selection whereby only suitable students should be allowed the privilege of continued education up to eighteen years of age.

Resolutions were adopted welcoming a large development of humane studies in the constituent institutions of the association in connection especially with adult education:—"That the association accepts the description of the work of a 'local college' contained in Appendix III. of the Draft Regulations of the Board of Education for continuation, technical, and art courses in England and Wales"; and "That each local college should be the recognised centre for the organisation of educational courses for adults in its area and for the supply of qualified lecturers and class tutors and adequate library and other facilities." It was resolved to refer to the council the question that the Board of Education should be asked to accept as "recognised service" the services of teachers engaged in organisation, supervision, and inspection with the view of qualifying such persons for pension under the recent Superannuation Act, and that the Board should furnish to every teacher of forty-five years of age and upwards a statement of his position as to the period of "recognised service" and "qualifying service" at present placed against his name for the purpose of pension.

The Asiatic Origin of Man.[1]

THE author of the speculative paper referred to below is an evangelist of the gospel of evolution according to Dr. W. D. Matthew. The idea of the Asiatic origin of the dominant orders of mammals, in its source as old as Buffon, was in 1915 placed on a firm basis by Matthew in his paper "Climate and Evolution." This idea Dr. Griffith Taylor now takes up and applies to the case of man. Penck's fourfold subdivision of the Ice Age is regarded as applying generally, and the development of the prehistoric races in Asia is presumed to occur in the successive mild periods as follows:

Chellian and Acheulian.	Pliocene.
Mousterian.	Gunz-Mindel.
Aurignacian, Solutrean, and Magdalenian.	Mindel-Riss.
Azilian and Neolithic.	Riss-Würm.
Bronze-using Races.	Post-Glacial.
Mongolians.	Late Post-Glacial and Historic.

The following Ice Age in each case and in post-Glacial times the progressive desiccation of Asia are presumed to have caused migration from the homeland to the peripheral continents. The migrations are thus fairly well timed to enable the respective races to keep their appointments in Europe, with, perhaps, the exception of the Chellians, Acheulians, and Mousterians, who are too early, if we may judge

[1] "Climatic Cycles and Evolution." By Dr. Griffith Taylor. *Geographical Review*, December, 1919.

by Penck's placing of these culture stages, which, however, rests only on indirect evidence.

Taking as his criteria of evolutionary advance four characters, namely, (1) cephalic index, (2) orbital index, (3) hair section, and, in a modified degree, (4) skin colour, Dr. Griffith Taylor then attempts an analysis of the existing races of mankind, and, so far as the available data permit him, shows that the more primitive races, or those with low cephalic and orbital indices and relatively flattened hair section (generally associated with depth of skin colouring), have been thrust to the more distant parts, from a migrant's point of view, of the outlying continents. Closer in to the centre of distribution come races with successively higher indices, rounder, straighter hair, and reduced colouring, passing through brown, olive, and white to the yellow, brachycephalic, and excessively straight-haired Mongolians, who are the last development of all. So far this is Dr. W. D. Matthew elaborated. A new element is now, however, introduced into the discussion, for an attempt is made to correlate the living with the prehistoric races. One remembers Sollas's tentative comparisons in 1911 ("Ancient Hunters"), viz. Tasmanian with Eolithic or Early Palæolithic, Australian with Mousterian, Bushman with Aurignacian, and Eskimo with Magdalenian. The author now postulates direct descent for these and many other races too numerous to mention here.

To bring out the nature of the climatic impulse that is supposed to have initiated the successive waves of migration from the homeland in Asia, the author employs the analogy of the seasonal oscillation of the belts of tropical rains, desert, and polar rains in Australia. As he effectively remarks, Nature has placed Australia like a blackboard, on which are recorded the results of the mobile but very regular and law-abiding climatic zones of the southern hemisphere. He brings forward evidence to show that these zones underwent an analogous migration during the climatic oscillations of the Ice age.

The analysis outlined above forms parts i.–iii. of the paper. The general exposition of the argument is crude, and, were it not for the explicitness of the diagrams, would be difficult to follow. This tabulating and precise definition of material largely speculative gives an illusory impression of the state of the subject, but, if the reader is not misled by it, it certainly conduces to clearness. The adroit handling of a subject so as to distinguish fact and legitimate inference from mere speculation is the last art of the scientific writer.

The remainder of the paper is devoted to geological speculations of less interest. Part iv. is an exposition of Chamberlin's theory of cyclic change. Chamberlin's writings (1897–1901) on the subject are not, however, quoted, the principal authority relied on being Schuchert (1914). In this section a table of roughly approximate temperatures is given for the periods from the Triassic to the present. That this type of tabulated speculation is dangerous is instanced by the fact that both zoological and botanical evidence show that the temperature of Europe in the Neolithic period was several degrees higher than it is at the present day, instead of 7° F. lower, as stated.

Part v. is an estimate of geological time based on various authorities. The statement is made that "Joly quotes similar figures, indicating about 300,000,000 as the time interval since the same epoch" (the Cambrian). It is difficult to conceive the author's motive, if any, for this implicit misrepresentation of the works cited, for it matters not a straw to his theory whether the interval since the Cambrian is 300,000,000 or less than 100,000,000 years, as concluded by Joly.

Part vi. is a suggestion, on astronomical lines, of rhythmic oscillations of climate, etc. It is on a par with many former theories of the Ice age in assigning a cause which there is no independent evidence to show was ever operative.

Papers such as this which deal in giddy speculation have for some time past been looked at askance by the more puritanically minded of our elder geologists. We are not sure that they deserve the contempt with which they are treated. In this matter, however, there is a golden mean, and we should have preferred to see the present paper made less comprehensive, and the leading subject-matter of human migrations more thoroughly dealt with. It is of no use trying to straighten out the universe in an article.

W. B. WRIGHT.

Long-range Forecasting in Java.

PUBLICATION No. 5, 1919, of the Royal Observatory of Batavia, entitled "Atmospheric Variations of Short and Long Duration in the Malay Archipelago and Neighbouring Regions, and the Possibility to Forecast Them," by Dr. C. Braak, embodies the results of a long investigation into the sequence of rainfall in the equatorial regions east of the Indian Ocean. Three kinds of variation are studied: (1) with periods of one or more years up to and including the sun-spot period, (2) secular variations, and (3) with periods less than a month, comparable with Abbot's short-period solar fluctuations. The variations, the period of which is intermediate between (1) and (3) above, are treated as disturbances of (1). Dr. Braak lays much stress on a three-year period, of the persistence of which he gives plausible, though not quite convincing, examples. He classifies three groups of years, of high barometer, low barometer, and transition (from high to low), but naturally finds a proportion of years not strictly true to any of these types. It is scarcely surprising that he finds in general a correlation between barometric pressure and rainfall. For the east monsoon he finds strong positive correlation between high pressure and drought, and weaker between low pressure and excess of rain. For the west monsoon he finds, with some local exceptions, excess of rain with high barometer, and deficit with low barometer. His problem is thus reduced to the intensity of the correlation and the chances of a correct forecast of the barometer variation. His next step takes into account temperature changes which may be expected to modify pressure conditions, but his result is disappointing. He obtains rules, but their application is so far a failure that they appear to break down most thoroughly in years of drought—that is, when, if correct, they would be most valuable

Turning to secular variations, he finds no evidence of progressive change in Batavian rainfall; in fact, the only progressive change on which he lays stress is in Batavian air-temperature. Comparison with stations in India, Australia, and other places in the same quarter of the globe provides other types of change, but none agreeing with Batavia, and the question is left unsolved.

There remain the short-period pressure waves. The equatorial manifestations of these he attributes to a kind of surge, caused by the great disturbances in higher latitudes, exercising a sucking influence or its converse, with slight variations of the rainfall, less than 10 per cent. of the normal, the effect of which is to compensate the pressure difference by cooling or heating air probably above the 3000-metre level.

Other variations of rainfall, humidity, and cloudiness he considers to be local, and, on the whole, rejects

the possibility of forecasting any short-period variations in the rainfall. Inasmuch as we are bound to regard the tropics as the first stage in the translation of solar variation into weather, it seems a pity that the result obtained in what is probably the best known region of the tropics in regard to meteorological statistics should appear so meagre and wanting in definiteness. Similar work in temperate regions may well be discouraged, but there is still an enormous mass of data W. W. B.

Insects of Arctic Canada.

THE insects of various orders—as well as a few spiders, mites, and centipedes—collected by members of the recent Canadian Arctic Expedition (1913–18) have been recorded and described in vol. iii. of the Report (Ottawa, 1919–20). The lists contain much information of value to students of zoological geography. Among the Lepidoptera (described by Arthur Gibson) it is interesting to see varieties of such well-known British butterflies as *Pieris napi*, *Papilio machaon*, and *Vanessa antiopa*. Most of the Coleoptera (by J. M. Swaine, H. C. Fall, C. W. Leng, and J. D. Sherman) belong to species already known in North America, and the same remark applies to the bees described by F. W. L. Sladen, who points out that bumble-bees are "particularly well adapted to Arctic conditions," and records the capture of five nearly full-fed Bombus larvæ on Melville Island (75° N. lat.) on June 21, 1916. The sawflies, described by A. G. MacGillivray, are mostly new species, and, as might have been expected, willow feeders. Among the Diptera (by C. P. Alexander, H. G. Dyar, and J. R. Malloch) there are some interesting details of larvæ as well as descriptions and records of flies, which are relatively numerous in species. The occurrence of larvæ of *Oedemagena tarandi*—the warble-fly of the European Reindeer—in Barren-ground Caribou at Bernard Harbour is noteworthy. Mosquitoes of a couple of species of the genus *Ædes* were observed (and felt) in swarms. As regards wingless parasites, Prof. G. H. F. Nuttall records that head-lice (*Pediculus capitis*) from the Copper Eskimo of Coronation Gulf show no varietal distinction from members of the species found elsewhere. Dr. J. W. Folsom enumerates a dozen species of springtails (Collembola); two only of these are new, but his figures of structural details, drawn carefully from Arctic specimens of common and widespread northern forms, will be welcome to students of this order.

G. H. C.

Earthquake Waves and the Elasticity of the Earth.

DR. C. G. KNOTT delivered a lecture on "Earthquake Waves and the Elasticity of the Earth" before the Geological Society on June 9. He pointed out that seismograph records of the earth-movements due to distant earthquakes proves that an earthquake is the source of two types of wave-motion which pass through the body of the earth, and a third type which passes round the surface of the earth. Before earthquake records were obtained, mathematicians had shown that these three types of wave-motion existed in and over a sphere consisting of elastic solid material. Many volcanic phenomena, however, suggest the quite different conception of a molten interior underlying the solid crust. At first statement these views seem to be antagonistic, but there is no difficulty in reconciling them. Whatever be the nature of the material lying immediately below the accessible crust, it must become at a certain depth a highly heated fairly homogeneous substance behaving like an elastic solid, with two kinds of elasticity giving rise to what are called the compressional and distortional waves. The velocities of these waves are markedly different, being at every depth nearly in the ratio of 1·8 to 1. Both increase steadily within the first thousand miles of descent towards the earth's centre, the compressional wave-velocity ranging from 4·5 miles per second at the surface to 8 miles per second at depths of 1000 miles and more; the corresponding velocities of the distortional wave are 2·5 and 4·3 at the surface and at the 1000-mile depth respectively. At greater depths these high velocities seem to fall off slightly; but the records fail to give us clear information as to velocities at depths greater than about 2500 miles. Down to this depth the earth behaves towards these waves as a highly elastic solid. The elastic constants, which at first increase with depth more rapidly than the density, become proportional to the density, for the velocity of propagation becomes practically steady. About half-way down, however, the material seems to lose its rigidity (in the elastic sense of the term), and viscosity possibly takes its place, so that the distortional wave disappears. In other words, there is a nucleus of about 1600 miles radius which cannot transmit distortional waves. This nucleus is enclosed by a shell of highly elastic material transmitting both compressional and distortional waves exactly like an elastic solid.

University and Educational Intelligence.

ABERDEEN.—Dr. R. D. Lockhart has been appointed a lecturer in anatomy.

It has been decided to institute a full-time lectureship in bacteriology in the department of pathology.

BIRMINGHAM.—It has been decided that the fees payable by new students entering the University next session shall be increased by 25 per cent. The reasons given for the increase are: (1) The great rise in the cost of administration, materials, maintenance, taxation, and the wages of employees; and (2) the necessity for improving the payment of the academic, particularly the non-professorial, staff.

The Vice-Chancellor (Sir Gilbert Barling), according to the *Birmingham Post*, states that "it is absolutely necessary to increase the stipends of the staff for two reasons: the present salaries are quite inadequate to maintain the teachers in a reasonable state of comfort; and, secondly, because without such increase they will be attracted to other places where stipends are more commensurate with their capacity and worth."

CAMBRIDGE.—The Balfour Memorial Fund studentship will be vacant on October 1 next. Applications are invited for it. Candidates should apply by, at latest, September 15 to Prof. J. Stanley Gardiner, Zoological Laboratory, Cambridge.

On July 29 the honorary degree of Doctor of Law was conferred upon Dr. A. L. Lowell, president of Harvard University; Prof. J. J. Abel, professor of pharmacology, Johns Hopkins University; and Prof. H. Cushing, professor of surgery at Harvard University.

OXFORD.—The fear expressed in some quarters that the application by the University for a Government grant would check the liberality of private benefactors has proved to be groundless in at least one con-

spicuous instance. Mr. Walter Morrison, of Balliol College, has just paid to Bodley's librarian the sum of 50,000*l*. for the capital account of the library. No further conditions are annexed to the gift. This is not the only benefaction for which the University is indebted to Mr. Morrison, for some eight years ago he gave 10,000*l*. to each of three funds—one for the readership in Egyptology, another for the promotion of the study of agriculture, and a third towards the establishment of a professors' pension fund.

THE Cairo correspondent of the *Times* announces that the American Presbyterian Board proposes to establish a university at Cairo, and has purchased a fine site for the building. The new University will be composed of five colleges, namely, arts, Oriental languages, teachers, commerce, and agriculture. It is stated that the first of these will be opened in October.

NOTICE is given that, provided sufficient merit be shown, an election to a fellowship in experimental physics or physical chemistry at Trinity College, Dublin, will take place in May, 1921. Candidates must submit papers or theses (published or unpublished) on or before March 25 next. Further particulars may be obtained from the Registrar, Trinity College, Dublin.

ON the occasion of the meeting of the British Association at Cardiff on August 24–28 the University of Wales will confer the honorary degree of D.Sc. upon the following:—Dr. H. F. Osborn, president of the American Museum of Natural History, or, if he is unable to attend, Prof. C. A. Kofoid, University of California; Prof. G. Gilson, University of Louvain, or, if he cannot attend, Dr. C. H. Ostenfeld, University of Copenhagen; Don Gullermo Joaquin de Osma, Madrid; and Prof. Yves-Guyot, Paris.

THE following subjects of wide educational interest are to be discussed at meetings of the Old Students' Association of the Royal College of Science, London, in the autumn:—September 14, Pre-Kensington History of the Royal College of Science and the University Problem in London, Prof. H. E. Armstrong; October 12, The Proposed University of Science and Technology: Can a Useful and Worthy University be based on Pure and Applied Science?, Mr. J. W. Williamson; and November 9, The Nationalisation of Universities, Viscount Haldane.

DR. R. S. CLAY, principal of the Northern Polytechnic Institute, Holloway, London, N.7, informs us that the governors are re-establishing in September the school of rubber technology at this Polytechnic, and that the school will in future be under the directorship of Dr. P. Shidrowitz, well known by his researches and publications on the chemistry and technology of rubber. There will be a day course open only to students who have had a thorough training in chemistry—preferably at one of the universities—and evening classes for those already in the industry. The school will be in close touch with the industry, as it will be under an advisory committee composed of representatives of the manufacturers, growers, dealers, rubber engineers, etc., and will, therefore, afford a sound theoretical and practical training for those proposing to enter a rubber factory.

THE May issue of *School Life*, issued by the U.S. Bureau of Education, shows that there has been a large increase in the demand for collegiate education during the ten years between 1905–6 and 1915–16. The period shows an advance, especially in public institutions, from 258,603 in 1905–6 to 387,106 in 1915–16, being an increase in the case of men of 40·1 per cent., and in that of women of 70 per cent. The number of teachers engaged has also risen from 23,950 to 31,312. The total income of these institutions has grown during this period from 62,499,931 dollars to 133,627,911 dollars, or 113 per cent., made up of students' fees 36,133,969 dollars, productive funds 18,983,868 dollars, United States Government 6,258,931 dollars, State or city 32,204,111 dollars, private benefactions 30,196,006 dollars, and other sources 9,850,326 dollars. The endowment fund increased from 248,430,394 dollars in 1905–6 to 425,245,270 dollars in 1915–16, or 71·2 per cent. A further table shows that during the last three years there has been a general increase of attendance of 25 per cent. at these institutions.

THE activities of the U.S. Department of the Interior (Bureau of Education) include the bi-monthly issue of a journal entitled *School Life*. That of May last is concerned largely with the question of the supply and remuneration of teachers, a problem apparently even more acute in America than in this country, as is instanced by the fact that on a given day in May the School Board Service Division of the Bureau of Education received 436 requests for teachers, with only seven teachers applying for posts. The chief of the Division reports that a year ago there were 14,000 registrations from teachers willing to take positions. A recent canvass of this list showed only about 4000 now available for service. The maximum average annual salary of teachers for any State is 1600 dollars, whilst the minimum is 93 dollars. The journal further deals with the payment of university teachers, and asks the question: Does it pay to be a college professor? The result of a recent inquiry circular sent out by the Bureau, to which more than two-thirds of the colleges and universities returned detailed and accurate answers, was that in privately supported institutions full professors are receiving on the average 2304 dollars per annum, while assistant professors and instructors draw salaries of about 1800 dollars and 1200 dollars respectively. The salaries of professors at State institutions average 3126 dollars, of assistant professors 2100 dollars, and of instructors 1400 dollars. There is an interesting table comparing the salaries in 1919 of professors, assistant professors, and instructors with those of artisans and labourers, much to the advantage of the latter in some cases.

THE development of social activities in the country districts is a problem of the first importance, and in the May issue of the *Journal of the Ministry of Agriculture* there is a most interesting paper entitled "Social Service in Rural Areas." The author, Sir Henry Rew, points out that if we are to maintain our agricultural output we must provide for the recreation of our farm labourers and their families. The conditions of village life, and, indeed, the whole psychology of the village people, have undergone great changes in the last few years. The young men returning from the Army to their native villages have found expression; the economic status of the farm-worker is improved; and, above all, there now exists a definite organisation of the farm-workers. These men are essentially a practical race; their ambitions are not restricted to increased wages; they simply make a reasonable claim that life shall not be merely a weary monotony of toil, but that there shall be opportunities for enjoyment—more than are afforded by the village alehouse. The demand is universal, and must be met without delay. In the Report of the Adult Education Committee it is suggested that every village should be provided with an institute under full public control. This institute should be the centre of all communal activity, educational, social, and recreational.

Societies and Academies.

SYDNEY.

Royal Society of New South Wales, June 2.—Mr. James Nangle, president, in the chair.—H. G. **Smith** and A. R. **Penfold**: The manufacture of thymol, menthone, and menthol from eucalyptus oils. Work was undertaken in order to determine the molecular structure of piperitone, the peppermint ketone of eucalyptus oils. Piperitone is a menthenone with the carbonyl group in the 3 position. When oxidised with ferric chloride in the ordinary way 25 per cent. of thymol was produced. By reducing piperitone with hydrogen in the presence of a nickel catalyst an almost quantitative yield of menthone was obtained, which on further reduction with sodium in aqueous ether produced menthol. The abundance of piperitone obtainable from *Eucalyptus dives* makes this ketone probably the best source for the manufacture of thymol and menthone.—R. H. **Cambage**: A new species of Queensland ironbark. This new eucalyptus comes from about 120 miles westerly from Cairns, in tropical Queensland, and furnishes a good, red timber. It was found growing on granite formation in open forest country, and resembles *E. crebra* in bark and timber, but differs in the shape of buds and fruits, which latter are hemispherical with exserted valves.

Progress!

THE word "progress" primarily signifies "a stepping forwards"—*forwards* not in relation to some real or imaginary goal the arrival at which we assume to be desirable, but merely in regard to the individual moving—in fact, a stepping "frontwards" as opposed to standing still or to stepping "backwards." In the course of the past few centuries it has, however, acquired a definite secondary limitation—that of the movement or development of human society towards a desirable goal—namely, earthly felicity, happiness, even perfection—or towards the attainment of perfect happiness in a future state of existence. The measure of "progress" thus necessarily has varied according to the conception of happiness—about which there have always been divergent opinions, and never an accepted definition. The philosophers of antiquity were pessimists: they did not entertain a belief in progress, but, on the contrary, held (with the notable exception of the Epicureans) that we are receding from a long-past golden age of happiness.

The notion of earthly progress was opposed by the Christian Church, which endeavoured to fix men's minds on a future state of rewards and punishments. A belief in the distribution of these by its intervention was the chief basis of the authority and power of the Church. The spirit of the Renaissance—the challenge to the authority of the ancients and of the Church, the emancipation of the natural man in the fields of art and of literature, and, later, in the sphere of philosophical thought—was accompanied by the development of the idea of progress. Ramus, a mathematician, writes in the year 1569: "In one century we have seen a greater progress in men and works of learning than our ancestors had seen in the whole course of the previous fourteen centuries." The French historian, Jean Bodin, about the same time, reviewing the history of the world, was the first definitely to deny the degeneration of man, and comes (as Prof. Bury tells us in the fascinating book which we have used[1] as the text of this article) nearer to the idea of progress than anyone before him. "He is," says Prof. Bury, "on the threshold." And then Prof. Bury proceeds to trace through the writings of successive generations of later philosophers and historians—such as Le Roy, Francis Bacon, Descartes, the founders of the Royal Society, and others, such as Leibnitz, Fontenelle, de Saint Pierre, Montesquieu, Voltaire, Turgot, Rousseau, Condorcet, Saint Simon, and Comte—the various forms which this idea of "progress" assumed, its expansions and restrictions, its rejection and its defence, until we come to the Great Exhibition of 1851, and, later still, to the new aspect given to the idea of progress by the doctrine of evolution and the theories of Darwin and of Spencer.

These chapters provide the reader with a valuable history of an important line of human thought. But the most interesting part to many of us must be the closing pages in which the actual state of the idea of progress as it appears in the light of evolution is sketched, and the questions are raised, which it has not been Prof. Bury's purpose to discuss, viz. Granted that there has been progress, in what does it consist? Is it likely to continue? Does the doctrine of evolution, now so firmly established, lead us to suppose that "progress" will continue, and, if so, what will be its character? Or is it (however we define it) coming to an end? Will stagnation, or will decay and degeneration, as some suppose, necessarily follow? Or is "progress" (whatever one may mean by that word) a law of human nature?

The doctrine of the gradual evolution of the inorganic universe had already gained wide acceptance before the epoch when Darwin's "Origin of Species" brought man into the area of evolution, and established the accepted belief in the "progress" of man from an animal ancestry to the present phase of the more

[1] "The Idea of Progress: An Inquiry into its Origin and Growth." By Prof. J. B. Bury. Pp. xv+377. (London: Macmillan and Co., Ltd., 1920.) Price 14s. net.

civilised races. It does not follow as a matter of course that such a development means the movement of man to a desirable goal. But (as Prof. Bury reminds us) Darwin, after pointing to the fact that all the living forms of life are lineal descendants of those which lived long before the Silurian epoch, argues that we may look with some confidence to a secure future of equally immeasurable length; and, further, that, as natural selection works solely by and for the good of each being, all corporeal and mental endowments will tend to progress towards perfection. Darwin was a convinced optimist.

Equally so was Spencer. According to him, change is the law of all things, and man is no exception to it. Humanity is indefinitely variable, and perfectibility is possible. All evil results from the non-adaptation of the organism to its conditions. In the present state of the world men suffer many evils, and this shows that their characters are not yet adjusted to the social state. Now the qualification requisite for the social state is that each individual shall have such desires only as may fully be satisfied without trenching upon the ability of others to obtain similar satisfaction. This qualification is not yet fulfilled, because civilised man retains some of the characteristics which were suitable for the conditions of his earlier predatory life. He needed one moral constitution for his primitive state; he requires quite another for his present state. The result is *a process of adaptation* which has been going on for a long time, and will go on for a long time to come. Civilisation represents the adaptations which have already been accomplished. *Progress means the successive steps of the process.* (There we have the scientific definition of human progress according to the apostle of evolution.) The ultimate development of the *ideal* man by this process (says Spencer) is logically certain—as certain as any conclusion in which we place the most implicit faith: for instance, that men will all die. Progress is thus held by Spencer to be not an accident, but a necessity. In order that the human race should enjoy the greatest amount of happiness, each member of the race should possess faculties enabling him to experience the highest enjoyment of life, yet in such a way as not to diminish the power of others to receive like satisfaction.

Let me say, in order to avoid misapprehension, that in what follows I am not citing Prof. Bury, but stating my own opinions and suggestions. It has been urged in opposition to the optimistic doctrine of Darwin and Spencer that it is a prominent fact of history that every great civilisation of the past progressed to a point at which, instead of advancing further, it stood still and declined. Arrest, decadence, decay, it is urged, have been the rule. This, however, is but the superficial view of the historian who limits his vision to the last four or five thousand years of man's development. It is not confirmed when we trace man from the flint-chippers of 500,000 years ago to the present day.

Naturalists are familiar with the phenomenon of *degeneration* in animal descent. Higher, more elaborate forms have sometimes given rise to simplified, dwindled lines of descent, specialised and suited to their peculiar environments. The occasional occurrence of such development in the direction of simplification and inferiority, and even the extinction of whole groups or branches of the genealogical tree of organisms, endowed with highly developed structural adaptations, and the survival of groups of extreme simplicity of structure, does not invalidate the truth of the conclusion as to a vast and predominating evolution —with increase of structure and capacity—of the whole stock of animal and vegetable organisms. A similar line of argument applies to the long and extended history of mankind.

The conclusion adverse to the reality of the evolutional progress of mankind which is held by those who declare that the ancient Greeks and other products of human evolution of like age had developed a degree of artistic execution and feeling, of devotion to intellectual veracity and ideal justice, to which more modern civilisation has not attained, is a fanciful exaggeration in which it pleases some enthusiasts to indulge. But an examination of the facts makes it abundantly clear that the conclusion is altogether erroneous.

Another attempt to discredit the belief in progress consists in an ambiguous use of the word "happiness" when it is declared that the teeming millions of China or even the herds of sheep browsing on our hill-sides are "happier" than the civilised peoples of Europe and America. Spencer's definition of the goal of human progress as determined by the general laws of organic evolution should lead in this discussion either to the abandonment of the use of the vague term "happiness," or to a critical examination of the state of feeling which it implies, and of the causes to which they are specifically related.

When we ask whether the conditions which have been the essential factors in human evolution and progress are still in operation and likely to operate for an indefinite period in the same direction, there is, it seems, in spite of the view as to their permanence held both by Spencer and by Darwin, room for doubt and for re-examination of the situation.

The struggle for existence, the natural selection thereby of favoured variations, and their transmission by physical heredity from parent to offspring, suffice to explain the evolution of man's bodily structure from that of preceding ape-like animals, and even to account for the development of man's brain to greatly increased size and efficiency. But a startling and most definite fact in this connection has to be considered and its significance appreciated. The fact to which I refer is that since prehistoric man, some hundred thousand years ago, attained the bodily structure which man to-day possesses, there has been no *further* development of that structure—measurable and of such quality as separates the animals nearest to man from one another. Yet man has shown enormous "progress" since that remote epoch. The brain and the mental faculties connected with it have become the dominant and only progressive, "evolving," attribute of man. And even in regard to the brain there is, since the inception of the new phase of development which we have now to consider, no increase of size, though were we able to compare the ultimate microscopic structure of the brains of earlier and later man we should almost certainly find an increased complexity in the minute structure of the later brain.

It seems to be the fact that—when once man had acquired and developed the power of communicating and receiving thought, by speech with his fellow-man (so as to establish, as it were, mental co-operation), and yet further of recording all human thought for the common use of both present and future generations, by drawing and writing (to be followed by printing)—a totally new factor in human evolution came into operation of such overwhelming power and efficiency as to supersede entirely the action of natural selection of favoured bodily variations of structure in the struggle for existence. Language provided the mechanism of thought. Recorded language—preserved and handed on from generation to generation as a thing external to man's body—became an ever-increasing gigantic heritage, independent of the mechanism of variation and of the survival of favoured variations which had hitherto determined, the organic evolution of man as of his ancestry. The observation, thought, and tradition of humanity, thus independently accumulated, continually revised, and extended, have given to later men that directing impulse which we call the moral sense, that still, small voice of conscience, the voice of his father-men, as well as that knowledge and skill which we call science and art. These things are, and have been, of far greater service to man in his struggles with the destructive forces of Nature and with competitors of his own race than has been his strength of limb and jaw. Yet they are not "inborn" in man. The young of mankind enter upon the world with a mind which is a blank sheet of "educable" quality, upon which, by the care of his elders or by the direction of his own effort, more or less of the long results of time embodied in the Great Record, the chief heritage of humanity, may be inscribed. From this point of view it becomes clear that knowledge of "that which is," and primarily, knowledge of the Great Record, must be the most important factor in the future "Progress of Mankind." Thus one of the greatest services which man can render to his fellows is to add to the common heritage by making new knowledge of "that which is," whilst a no less important task is that of sifting truth from error, of establishing an unfailing devotion to veracity, and of promoting the prosperity of present and future generations of his race by facilitating, so far as lies within human power, the assimilation by all men of the chief treasures of human experience and thought.

The laws of this later "progress" are not, it would seem, those of man's earlier evolution. What they are, how this new progress is to be made more general and its continuance assured, what are the obstacles to it and how they are to be removed, are matters which have not yet been adequately studied. The infant science of psychology must eventually help us to a better understanding. Not only the reasoning intelligence, but also the driving power of emotion must be given due consideration. "Education" not only of the youth, but also of the babe and of the adult, must become the all-commanding interest of the community. Progress will cease, to a large extent, to be a blind outcome of natural selection; it will acquire new characteristics as the conscious purpose of rational man.

E. Ray Lankester.

Complex Elements in Geometry.

The Theory of the Imaginary in Geometry, together with the Trigonometry of the Imaginary. By Prof. J. L. S. Hatton. Pp. vii+215. (Cambridge: At the University Press, 1920.) Price 18*s*. net.

WHEN we interpret $\phi(x, y)=0$, $\psi(x, y)=0$ as the point-equations of two loci, we are bound to consider any values (x_i, y_i) which satisfy both equations as the co-ordinates of a point common to both curves. The simplest case is when ϕ, ψ are polynomials with ordinary integral coefficients; here the values (x_i, y_i) are determinate, and can be calculated, either exactly or to any desired degree of approximation. Abstractly, (x_i, y_i) are a perfectly definite set of couples of algebraic numbers. A couple (x_i, y_i) may be real, and then corresponds to a real point; but it may be, and often is, complex. What is the most appropriate and fruitful way, from a geometrical point of view, of interpreting these complex solutions of the given pair of equations? This is one of the fundamental problems of analytical geometry, and there are two ways in which it may be attacked. Suppose that the coefficients of ϕ, ψ are real, complex intersections (x_i, y_i) fall into conjugate pairs. The usual analytical formula gives a real line as the join of two conjugate points, and we may call this a common chord of the two loci. The visible result of combining $\phi=0$, $\psi=0$ may be said to be a certain number of real intersections and a certain number of real lines which, from an algebraical point of view, are to be regarded as common chords. The most familiar case is that of two circles and their radical axis; and here we have a geometrical definition of the radical axis which applies whether it meets the two circles or not. We can construct a definition of a common chord of two conics by analogy, whether it meets them in two real or two conjugate complex points; but the procedure is artificial, and there is no obvious way of extending it to higher curves.

The other way is to try to find, as the image or representative of (x, y), when x, y are not both real, some definite constructible geometrical entity to which we can give the name of "point" *without violating the axioms of projective geometry*—*e.g.* it must still be true that any two points determine a line, and so on. This, of course, involves an appropriate definition of a complex line.

It is to von Staudt that we owe an absolutely perfect solution of this difficult problem. Its basic idea is this: Given a real conic, and a real line which does not cut it (in the ordinary sense), there is on the line an elliptic involution of pairs of points conjugate to the conic. With this elliptic involution we can associate either of two opposite "senses" (or directions), and we can interpret the involution, with either sense, as a complex point. These complex points are distinct, and conjugate in a sense analogous to the algebraic one. This geometrical distinction of conjugate complex points appears to have been the one thing with which von Staudt had the greatest difficulty; it must be remembered that he was trying to find a theory applicable to three dimensions as well as to two, and that he wanted to define the line joining *any* two points in space whether real or complex, and this by purely projective considerations. The "join" of two non-conjugate complex points in space is von Staudt's "line of the second kind," and the most difficult to realise of all his concepts.

What we may call a metrical, or Cartesian, image of a complex point $(a+bi, c+di)$ is a segment $\overrightarrow{OP}$ drawn from the real point (a, c) to the real point $(a+b, c+d)$. The conjugate point is represented by a segment $\overrightarrow{OP'}=-\overrightarrow{OP}$, and these two conjugate points are on the real line PP′. Poncelet, following that Will-o'-the-Wisp, the "principle of continuity," very nearly hit upon this representation; for if we consider $x^2+y^2=a^2$, $x=b$ $(b>a)$, we have as the intersections $(b, \pm i\sqrt{b^2-a^2})$, which, in this representation, are the principal ordinates of the real hyperbola $x^2-y^2=a^2$.

Prof. Hatton practically adopts this metrical definition, but in doing so, as it seems to us, introduces unnecessary vagueness, and occasionally wabbles between the two points of view. He begins by an "axiom" which von Staudt breaks up into two definitions, and, so far as we can see, ignores it in all his algebraical "verifications." There is no such thing as an algebraical verification in the true theory. The algebra is taken for granted, and we have to show that our geometrical definitions and postulates and axioms agree with ordinary complex algebra. In the Cartesian representation a point which we may call $(\overrightarrow{OP})$, or more simply (OP), corresponds to von Staudt's representation (O ∞PP′), where O bisects PP′, and ∞ is the point at infinity on the real line POP′.

So long as we keep to von Staudt's projective definition, the questions of such things as "distance," "angle," etc., do not arise. "Sense" and "order" are essential, the latter especially when we consider von Staudt's theory of "casts" and cross-ratios.

It is in connection with the Cartesian imagery

that we are confronted with questions about distances, angles, and so on. We are bound to interpret the distance (δ) between the points $(a+bi, c+di)$ and $(a'+b'i, c'+d'i)$ as given by

$$\delta^2=\{(a-a')+(b-b')i\}^2+\{(c-c')+(d-d')i\}^2,$$

and there are corresponding theorems about angles.

On the whole, we think Prof. Hatton's book will be most useful in suggesting ways in which the Cartesian way of regarding complex points (and lines) is brought into line (without sacrificing logic) with the projective theory. What we may call the complex point (OP), meaning the involution (with a definite sense) of which O is the centre, and $-OP^2$ the invariant $(OQ.OQ'=-OP^2)$, is a perfectly definite idea, and is a special case of von Staudt's representation of any complex point in the harmonic form $(O\infty PP')$ or $(O\infty P'P)$ with the initial point O.

Von Staudt's theory is purely projective, apart from the discussion of improper casts. The Cartesian theory is bound to deal with metrical quantities, such as distance and angle, and simply because these notions are derivative, it offers a field of research of a more complicated character. It may be asserted with some confidence that any real extension of von Staudt's theory will be of a metrical kind, and that, if it is worth anything, it will be applicable to three dimensions (or more) as well as to two. G. B. Mathews.

P.S.—Since the above was written, I have had time to reflect further upon Prof. Hatton's book, and have read Prof. G. H. Hardy's review of it in a recent number of the *Mathematical Gazette*. I do not wholly agree with Prof. Hardy's attitude, because I still think that there are geometrical notions not reducible to arithmetic—still less to formal logic. But I do agree with him that Prof. Hatton's book has no theoretical value, and, disagreeable as it is, I think it is my duty to say so, especially as I have been informed that another reviewer has praised the book in absurdly exaggerated terms. G. B. M.

Motion Study and the Manual Worker.

Motion Study for the Handicapped. By Frank B. Gilbreth and Dr. Lillian Moller Gilbreth. (Efficiency Books.) Pp. xvi+165. (London: George Routledge and Sons, Ltd., 1920.) Price 8s. 6d. net.

THE work of Mr. Frank B. Gilbreth upon applied motion study and fatigue study is well known, and the present volume describes various extensions and additions to his previously recorded methods, especially with the intention of assisting men who are handicapped by the loss of a limb or of their eyesight. In Mr. Gilbreth's latest scheme the manual worker whose movements are being studied has a small electric light attached to the hand or other working member of the body, and thereby the path of the motions made can be determined in detail if a series of photographs is taken by kinematograph. Other photographs are taken with a stereoscopic camera, and by this means the path of the motion in three dimensions is ascertained. It is then possible to construct wire models showing exactly the path of a given motion, and such models are found to be very useful for instruction purposes. Series of models are exhibited at the Smithsonian Institution, Washington, and elsewhere, so that skilled mechanics are able to see for themselves what are considered to be the best methods of performing certain motions, and to determine if they themselves fall short of the ideal.

Again, Mr. Gilbreth represents on diagrams, termed "simultaneous-motion cycle charts," the results of his studies on micro-motion. Such charts, when read downwards, present in chronological sequence the various activities performed by any member of the body, the posture taken during the action, and the time consumed. If read across, the charts give a record of all the working members of the body at any one time, and they enable one to see which parts of the body are working most and which are being delayed. It is maintained that this chart system enables the workmen to visualise their efforts graphically, and thereby to lessen waste and increase efficiency.

The great ingenuity of Mr. Gilbreth's methods will be admitted by everyone, but it is more important for us to determine their practical value. Mr. Gilbreth photographs champions playing baseball, champion typists, skilled surgeons when operating, in addition to skilled tradesmen, and he believes that the skill shown is in every case based on one common set of fundamental principles, the principles of economy of effort and rhythm of motion. The application of this hypothesis to practical ends is, however, very far distant. The concrete instances quoted of the employment of micro-motion study in actual practice are very few and not very striking, but doubtless it will take a good deal of time before they can be adequately tested and applied.

The portion of the book devoted specially to the handicapped describes several useful methods, though it strikes the uninitiated that they could have been evolved equally well without elaborate micro-motion study and motion-cycle charts. The one-armed typist is supplied with a typewriter

which has a magazine of paper lasting him a week, and he is enabled to type four copies at once by means of ribbons instead of carbon paper. The blind man is trained by visualisation, and is taught to use a cross-sectioned visualising board, on which the tools and equipment he is using are placed at fixed points. Thereby great waste of time and effort is saved. The importance of finding work that cripples can do, and of teaching them to do the work, is insisted on. Not only have the war cripples to be considered, but also the very numerous workers crippled as the result of industrial accidents. H. M. V.

Our Bookshelf.

Engrais. Amendements Produits anticryptogamiques et Insecticides. Par Dr. E. Demoussy. Pp. xi+297. Paris and Liége: Ch. Béranger, 1919. Price 15 francs.

Dr. Demoussy's manual on the analysis of fertilisers is written for the trained chemist; it is founded on the methods laid down in 1897 by the Comité des stations agronomiques, but unofficial methods in use in the principal French laboratories are also described. After a short introduction on the laws regulating the sale of fertilisers, the author deals in the first two chapters with the collection of samples and their qualitative examination. The following four chapters treat of the determination of nitrogen, phosphoric acid, potash, and manganese, the arrangement being according to the substance to be determined, and not the material in which it is found. The methods are for the most part well known in this country, and call for only a few remarks. The longest section is that devoted to nitrogen. The official method for nitrates is that of Schloesing, and no mention is made of the zinc-copper couple, while for organic nitrogen the Kjeldahl and soda-lime processes are both recommended. The latter has fallen into almost complete disuse in this country, and probably few chemists here would agree with the opinion that it is the more economical in time when many samples are to be examined. Where a purely chemical analysis would be of little value, as in the case of dried blood, drawings of the materials as seen under the microscope are given. The value of these would have been greatly increased if the magnification had been stated. Under the head of potash no reference is made to flue-dust; in this case the official methods would have to be slightly modified to ensure complete removal of silicic acid.

The second and third parts of the book deal with materials such as lime and with fungicides and insecticides. Tables for the calculation of results are added, and the appendix contains the French laws and regulations dealing with the sale of fertilisers.

The book is well arranged and clearly written, and its value is added to by notes on the form in which the various materials are put upon the market and the adulterations to which they are liable. It should prove very useful in analytical laboratories in this country as well as in France.

Donald J. Matthews.

Flora of Jamaica: Containing Descriptions of the Flowering Plants known from the Island. By William Fawcett and Dr. Alfred Barton Rendle. Vol. iv., *Dicotyledons: Families Leguminosae to Callitrichaceae.* Pp. xv+369. (London: British Museum (Natural History), 1920.) Price 25s.

The fourth volume of this admirable tropical flora has lately appeared, and contains the Dicotyledons from Leguminosæ to Callitrichaceæ (on the Englerian system). It maintains the high standard of its predecessors, and shows a great advance upon some well-known tropical floras in being illustrated by excellent text figures, and not by a series of separate plates, which are usually troublesome to consult. The index is also convenient in being only a single list of both scientific and popular names and synonyms. Turning to the contents of the book, which have been worked up with much care and after consultation of all the older authors and collections, an interesting feature that may be noticed is the extraordinary generic similarity of the flora to that of other islands, even at immense distances from Jamaica. In the Leguminosæ, for example, the first family in the volume, 118 Jamaica species, or 80 per cent., belong to genera that also occur in Ceylon, 74 per cent. to genera occurring in Formosa, and even in the case of so far distant an island as New Caledonia 63 per cent. of the Jamaica species belong to common genera. It is clear that the islands on the whole contain the older genera, which have been able to reach them. Of the Jamaica genera of Leguminosæ 70 per cent. are cosmotropical, and only 14 per cent. are confined to the New World. Again, one notices that the proportion of endemic species is small in Leguminosæ, and larger in Euphorbiaceæ and some of the other families, just as in other floras. It would appear a promising piece of work to make a careful statistical study of numbers and proportions of endemics in many countries, for it evidently follows definite, if perhaps recondite, laws.

Butter and Cheese. By C. W. Walker Tisdale and Jean Jones. (Pitman's Common Commodities and Industries.) Pp. ix+142. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

The writers of this book have succeeded in giving to the general reader a very good account of the essential facts in connection with the dairying industry. As was to be expected, it was necessary to treat the subject on what are generally termed popular lines, but certain of the chapters are written in a particularly clear manner and with full regard to the essential technical points. Not only the chief branches of the dairy industry—cheese-making and butter-making—are dealt with, but also the production of milk, the methods of analysis, and the judging of dairy produce are

touched upon. In connection with the production of milk it would have been useful to include a short account of the practice of milk-recording, for the general reader has but little idea of the system and the benefits it confers.

The methods employed in separating cream and preparing it for churning are fully dealt with, and the chief machinery, such as the separator, the cream ripener, the regenerative heater, and the pasteuriser are described.

Cheese-making is dealt with by taking Cheddar cheese as a type, and the principles and practice are fully explained, as are also the essential points in the maturing and marketing of the produce.

Notes on judging cheese and also butter are given, and should prove helpful, whilst attention is directed to the advantages which have followed the control of butter in Denmark and cheese in New Zealand. The reproach still to be heard that a lot of home produce is not of the quality that might reasonably be expected is probably warranted, but a great deal is being done to teach proper methods, and an improvement in quality may be expected throughout the country in the near future.

Elgie's Weather Book: For the General Reader. By Joseph H. Elgie. Pp. xii+251. (London: The Wireless Press, Ltd., 1920.) Price 5s. net.

THIS work is essentially for the uninitiated in weather study. The author presupposes no technical knowledge, and has throughout avoided mathematics and formulæ. A rough survey is taken of elementary meteorology in a way which must commend itself to all who take an interest in ordinary weather changes. In the opening sentences the author appeals to boy or man; he might also as well appeal to the other sex, who are now taking a keen interest in all branches of science.

The book is divided into fifteen chapters, which separate the subject into well-recognised divisions. A weather vocabulary is given at the end which the reader will find helpful, and in this, as well as in the general text, the latest official and recognised publications have been consulted, which is an immense advantage, as meteorology at present is making rapid strides in its advance.

Weather and health are doubtless intimately associated, and in this respect reference is made to the close relationship between rainfall and diphtheria, as shown by Sir Arthur Newsholme, the disease varying inversely with the amount of rain. There are few points in the book with which a meteorologist could find fault, and the author certainly imparts a large amount of useful knowledge.

Selected Studies in Elementary Physics: A Handbook for the Wireless Student and Amateur. By E. Blake. Pp. viii+176. (London: The Wireless Press, Ltd., 1920.) Price 5s.

WE have here something of a short cut to knowledge which occupies a peculiar position in scientific literature. Addressed to those already familiar with the phenomena of wireless telegraphy, it assumes some knowledge of electrical matters on the part of the reader, a little mathematics, but an almost complete ignorance of the physical and chemical properties of matter. We do not say that this attitude is necessarily unsound, as there must be many "amateurs" who have tried to run in pursuit of electrical subjects before they could walk, and it is praiseworthy to endeavour to teach them to walk by a quick method, as they are not likely to possess the time or the temperament to plod through more laborious courses. Granted, then, that there is a justification for presenting the elements of physics and chemistry in such a severely compressed form, the author displays skill in dealing with his difficult task, although there are some inconsistencies in the degree of knowledge that he assumes his reader to possess. We like, among other things, the way in which the author encourages the student to think in vectors early in his career, and to keep continually in mind the dimensions of the quantities that he is considering. If the reader is enabled, by taking advantage of the guidance offered, to form scientific habits of thought which he would not have acquired otherwise, the book will be a success.

The Coolidge Tube: Its Scientific Applications. Medical and Industrial. By H. Pilon. Authorised translation. Pp. v+95. (London: Baillière, Tindall, and Cox, 1920.) Price 7s. 6d. net.

M. PILON has not been so careful in selecting a translator for his little book on the Coolidge tube as he was in the original material. The French version was excellent, both from the practical point of view and the judicious selection of data bearing upon recent developments in radiography. Curiously enough, passages which in the original present no difficulty to the reader now lack that clearness which any translator should carefully preserve. We select a paragraph which explains the first figure in the text: "This rising part, denoted by *e*, is on account of the electrons, by traversing from one electrode to the other under the influence of a large potential difference, acquiring such a speed that on encountering gas molecules, they split up. . . ." Again, on p. 17, in describing the radiator type of tube, we read: "The limiting power it is capable of bearing oscillates between 500 and 600 watts."

We notice that the letterpress of many of the diagrams remains in the French language. The developments of the Coolidge tube and the uses to which it may be put will doubtless necessitate a further edition by M. Pilon, and we trust that he will then give the English edition more careful consideration.

Techno-Chemical Receipt Book. Compiled and edited by W. T. Brannt and Dr. W. H. Wahl. Pp. xxxiii+516. (London: Hodder and Stoughton, Ltd., 1919.) Price 15s. net.

THIS book contains a very large number of recipes covering an amazing field. As might be expected,

many of these are of questionable value, either on account of the methods having been replaced by more up-to-date processes or because the materials specified, which were by-products of long-vanished industries, cannot now be obtained. Apart from this defect, which is inherent in all books of this type, there is no doubt that the present volume will be of great service to workers in laboratories as well as to those engaged in industry. The authors state that "the materials have been principally derived from German technical literature, which is especially rich in receipts and processes which are to be relied on." From the impossible nature of several of the processes, one might have guessed this: British workers are familiar with the "reliable" character of some German specifications.

Photography and its Applications. By William Gamble. (Pitman's Common Commodities and Industries.) Pp. xii+132. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

Mr. Gamble, having had a lifelong experience in connection with technical photographic processes and their applications, speaks with authority on these matters. But the very limited scope afforded by so small a volume as this, and the innumerable applications that have to be dealt with, give him only a poor opportunity of presenting the subject to his readers. The short summary often passes into a mere catalogue of operations, and this into a mere dictionary-like mention. A little more care might well have been bestowed on the revision of the text. Working instructions are not given. We can recommend the book to those who wish to get in a small compass a general, but superficial, knowledge of the character of photography and its applications.

The Chemists' Year Book, 1920. Edited by F. W. Atack, assisted by L. Whinyates. Vol. i., pp. vi+422; vol. ii., pp. vii–viii+423–1136. (London and Manchester: Sherratt and Hughes, 1920.)

Succeeding editions of this handy laboratory manual are increasingly useful. The present volumes supply the need formerly satisfied by the "Chemiker Kalender"; English chemists have now no necessity to go outside their own country for such books. A valuable feature of "The Chemists' Year Book" is the series of articles written by specialists, such as that on "Alkaloids" by Dr. E. Hope. The tables and numerical data are very complete.

Ions, Electrons, and Ionising Radiations. By Dr. J. A. Crowther. Pp. xii+276. (London: Edward Arnold, 1919.) Price 12s. 6d. net.

The subjects dealt with include gaseous conduction, thermionic emission, photo-electricity, X-rays, radium rays, and the electron theory. The treatment involves a knowledge of elementary mathematics, and the work forms a useful appendix to the ordinary text-book of physics. A clear and very readable account is given of the "quantum" theory of radiation.

Letters to the Editor.

University Grants.

The article on university grants in Nature of August 5 is opportune, and does not overstate the gravity of the situation. The proposed recurrent half-million is welcome, but quite inadequate. The annual grant to the universities of the United Kingdom should be at least three millions.

We have been rigidly economical in our expenditure. There is no question of the value of the work which has been done. Everyone agrees that vigorous and well-found universities are indispensable to the national welfare, but they are hampered at nearly every point by insufficiency of income. Large numbers of their teachers are very seriously underpaid. Many departments are undermanned. Advanced studies and research are lamentably curtailed. Libraries are stinted of necessary books.

Before prices rose the universities had not the financial resources which their work required. Since the change in the value of money their position has become critical; some of them are threatened with disaster. In Leeds we have done everything in our power to raise salaries in order to meet the increased cost of living. The emergency was so grave that we decided to run a great risk. We have incurred obligations which will entail an annual deficit of 25,000*l*. Even this expenditure falls far short of what should be incurred if the high standard of university teaching is to be maintained permanently. It will be impossible for us to continue the present rate of expenditure unless large new grants are forthcoming. In the absence of further aid from the Government I see nothing for it but the abandonment of work which is now well done, indispensable, and nationally advantageous. We need an additional income of about 60,000*l*. a year in order to maintain the supply of teachers of the right type. The annual grant from the Government to the universities of the United Kingdom should be three times as large as what is given this year.

M. E. Sadler.

The University, Leeds, August 9.

The Carrying Power of Spores and Plant-Life in Deep Caves.

My sister and I observed a similar growth of vegetation to that which Mr. Lough. Pendred describes in the Cheddar Caves in Nature of August 5, p. 709. We were on a knapsack-walking tour together in the Hartz Mountains in 1900, and saw this effect in the beautiful, great, deep Rübeland Caves. These were then lit up by both oil and electric lamps placed, as in the Cheddar Caves, in recesses or on the floor so as to illuminate the stalactites and bone remains. We were told that the ex-Kaiser had ordered the electric illumination, not being content with the previous oil lamps, but both kinds of lighting were still there.

It was very noticeable that the vegetation spread out fan-like in front of the electric lamps to a much greater extent than behind them, or than near the oil lamps, and yet the electricity must have been, at that date, of fairly recent supply. It is true that the

oil lamps are more likely to have had an indefinite position, as they must be handled to fill, but they have probably been much longer close to the situations in which we saw them. The less vegetative growth round them and the shadow effect behind the electric lamps would seem to show that it was the shorter light-waves which were requisite for this plant-life rather than contact-warmth or longer heat and reddish light.

With regard to the transport of the spores to the depths of the caves, some experiments by Profs. Zeleny and McKeehan are of interest. At the Winnipeg meeting of the British Association in 1909 they read a paper, followed by a discussion, on experimental verifications of Stokes's law for the fall of spherical bodies in a viscous fluid. They deduced a discrepancy between theory and experiment which would seriously affect the cloud estimate of gaseous ionisation. A fuller paper and further experiments were published in *Physikalische Zeitschrift* for February, 1910, in which they showed that while a cloud of minute smooth paraffin spheres or mercury droplets obeyed Stokes's law, yet similar experiments with the spores of Lycoperdon, Polytricium, and Lycopodium (all nearly spherical) gave only about half the terminal velocities required by mathematical theory. In NATURE of January 6, 1910, I offered an explanation of the apparent discrepancy shown by their results. By using a large-aperture microscopic objective with oblique illumination and spectrum-sifted blue solar light, the spores can be seen, just within the limits of visibility, to be coated with a mass of very fine hairs more than a radius in length. Substituting in Stokes's formula for the terminal velocity

$$v=\frac{2}{9}\frac{ga^2d}{\mu},$$

where a is the radius, μ the air viscosity, and d the density of the spores, the effective diameter comes out to be just double that of the measured diameter as seen in an ordinary microscope. This increase of effective diameter is what should be expected if a mass of air be entangled with the spore, or a tail of eddies formed. Hence the physical measurement of the terminal velocity of fall confirms the microscopic observation of the hirsute coating in all the three sets of cases where spores were used. The spores are enabled to be wafted great distances, therefore, much as are the seeds of a dandelion. No Brownian motion or rotation was observed, and this also suggests the coating of hairs. Since the spore-walls are not absolutely spheres or smooth in the sense that surface tension makes the droplets, some Brownian motion would have been expected if the external air molecules could strike directly on the spore-wall. The air entangled in the *chevaux de frise* of hairs will, however, soften down the average result of individual impacts of external air molecules by making the effect slower, and therefore the resultant average smoother.

Yet another indication of this coating of long hairs is the difficulty of wetting Lycopodium dust until it has lain on the water long enough to get water-logged, viz. long enough, probably, for the entangled air to be dissolved out. While the air is so entangled the effective density is more nearly one-eighth than a little above unity as measured by Profs. Zeleny and McKeehan.

That this hairy coating provides these spores with a special mechanism which enables them to be carried great distances, is only to make them resemble many other wind-borne fruits, and the fact is therefore likely from general considerations.

The method of verifying a difficult, almost ultra-microscopic, observation in botany by measuring the terminal velocity, as of a small falling body in a viscous fluid, is perhaps not common.

EDITH A. STONEY.

King's College for Women, London.

Curious Formation of Ice.

IN NATURE of December 12, 1912, was published a letter wherein I described a curious formation of ice in the hope that some of your readers would be able to explain the cause, but there was no reply. After five years the formation occurred again in similar circumstances, and I submit a partial explanation which occurred to me on seeing this second example of the phenomenon. The ice was again formed on water in a rough hole or pond (about 2 ft. by 1 ft.) in the garden in clay soil. It was observed at 3.30 p.m. on January 13, 1918. The "dark, sinuous lines" in this case were about ⅛ in. wide, and again ran "about parallel to the major axis" of the small pond. These dark lines were again due to the ridges of ice on the under-side of the ice covering the water, but were closer together than before, being about 1½ in. apart. The cross-section of the ridges was again of "dovetail" shape, the attachment being at the smaller end of the "dovetail."

The partial explanation appears to be as follows: A uniform layer of ice about ¼ in. thick forms over the whole surface of the water. The water slowly leaks out of the pond. The ice sags in the middle, keeping in contact with the water over its central area, but, owing to the support of the sides of the pond, the edges do not sag, and an air-space forms under the ice round its margin. The vertical cross-section of this air-space is a long, narrow triangle lying on one long side (the free surface of the water); the under-side of the ice forms the other long side, and the mud-bank of the pond the short side. At night, or at any other time when the temperature again falls below freezing point, the water at the margin (where the ice and surface of the water meet at an acute angle) freezes to the slab of ice and forms a ridge on the under-side of the ice. The water leaking slowly from the pond all the while would help the formation of the ridge. The next day, or when the temperature is again slightly above freezing, the water, continuing to leak away, allows a further slight sagging of the ice and the enlargement of the air-space, thus giving the space between the ridges of ice. The next freezing forms the second ridge, and so on.

This explanation appears to account for the ridges, their spacing, and their being roughly parallel to the major axis of the pond, but it does not account for the beautifully sharp, regular, and symmetrical formation of the cross-section of the ridges. One expects an asymmetrical cross-section instead of the symmetrical "dovetail." It has been suggested to me that the "dovetail" shape is due to the ridge being partly melted (where it is joined to the top slab of ice) during the period when the temperature is above freezing by the comparatively warm top surface of the water. This seems to be a possible explanation if the cross-section of the ridge when first formed is rectangular.

I hope that with this as a basis someone will be able to complete or modify the explanation of the curious formation of ice observed.

Bees and the Scarlet-Runner Bean.

Darwin directed attention to the slight asymmetry in the petal growth of the scarlet-runner bean, *Phaseolus multiflorus*, that offered advantage to the bee for more easily reaching the nectar on that side of the flower where fertilisation would be helped by the visiting insect. I remember some years ago many times satisfactorily confirming the recorded fact by observation, but this year I am surprised to note quite a different practice in respect to insect visits to these flowers.

The humble-bees follow the habit they have long acquired in rifling the tubular flower of the jasmine of its honey: that of gnawing a hole near the base of the corolla, through which the proboscis can reach and extract the nectar. A similar plan is now adopted with the flower of the scarlet-runner bean. The bee no longer dives into the more open side of the bloom, where it would brush against the protruding anthers and stigma in an endeavour to reach the nectaries at their base, but on alighting moves immediately to underneath the blossom and, if not already done, gnaws through the calyx and sheath of filaments close to the nectaries, which are then easily reached and emptied. The honey-bees follow, and this season I have observed no instance of an insect attempting to reach the honey in the way the development of the flower suggests as that of reciprocal advantage.

The asymmetry of the bloom is due to the peculiarly coiled shape that the carina or keel part of the papilionaceous corolla develops. This causes the stamens and pistil to take a spiral form as they grow through and protrude together from the extremity of the enveloping carina, and exposes them between the more separated left wing and standard petals.

Though perfectly adapted to self-fertilisation, the flower, by the change of habit of the bees, would appear to lose the occasional advantage of cross-pollination, and the injury done by the gnawing of the bloom apparently causes a diminution in the amount of pollen formed and a quicker fading and falling of the bloom, with the probable consequence of fewer pods "setting."

The Museum, Torquay.

The Condition of Kent's Cavern.

Since a recent visit to Kent's Cavern I have been wondering if it would be possible for something to be done by which any important finds that may be made there could be brought to the notice of those interested in ancient man. The cave now seems to be one of the sights of Torquay which any curious visitor can see, just as he visits the caves elsewhere when on a holiday. There is a well-informed man who shows the sights to visitors, and he stated to a party, of which I was one, that quite recently a jaw of a human being had been found, and that this was in the possession of a local collector. A human tooth has also been found. It seems highly desirable that the jaw should be examined by a competent authority. During the famous excavations which were made some years since a jaw was found, but this was examined and described only a year or two ago; and although Prof. Keith thought that it represented the Neanderthal type in this country, I believe Dr. Duckworth pronounced that it did not differ from modern races. If this further jaw were examined the question might be settled, and it would be of great interest if it were found that, after all, the race was actually represented in this country.

Calculation of Vapour Densities.

When determining vapour densities I believe that many, if not most, experimenters go through three processes, viz.: (1) Correct the observed volume to that at N.T.P.; (2) find the mass of hydrogen which would occupy this latter volume; and (3) divide this mass of hydrogen into that of the substance used, whence density d on the *hydrogen standard* is found.

Now if we evaluate the constant R in the gas equation $pv = RT$, using mm. of mercury-column as units of pressure p, and taking v as the gram-molecule in litres—which on the *oxygen standard* at N.T.P. is 22·4 litres—we get the figure 62·36.

Then, for finding density, the equation becomes

$$d = \frac{mRT}{2pv},$$

where m is the mass in grams and v is in litres.

To quote an example: 0·5 gram of iodine expelled 50 c.c. of air at 17° C. and 750 mm. from V. Meyer's apparatus. Was the temperature to which the iodine had been subjected high enough to cause dissociation?

This problem, if done by the "three processes," takes some time, and gives $d = 119{\cdot}6$, which now requires to be multiplied by 1·008 if we wish to compare it with published figures for atomic weights ($119{\cdot}6 \times 1{\cdot}008 = 120{\cdot}56$).

Using the single equation given above,

$$d = \frac{0{\cdot}5 \times 62{\cdot}36 \times 290}{2 \times 750 \times 0{\cdot}05} = 120{\cdot}5.$$

The answer to the problem is evident. Slight dissociation had occurred, since d for I_2 demands 126·9.

I venture on these remarks because R is seldom, if ever, given in the above-mentioned units. It is expressed usually in such units as are suitable for solving energy problems. This number, 62·36, is an "equator" of the four steps which themselves, no doubt, are valuable from an educational point of view. Readers of Nature who are engaged in science teaching may find the "equator" of some service.

Reginald G. Durrant.

Rosetree, Marlborough, July 31.

Use of Sumner Lines in Navigation.

Capt. Tizard's reference to my book entitled "The Sumner Line," etc. (Nature, July 1, vol. cv., p. 552), contains an error which should be corrected. His statement regarding what he calls the zenith point, "which spot is named by Mr. Comstock the sub-polar point," seems to imply that I have introduced a new name not approved in the criticism that follows. In fact, I have nowhere used the obnoxious term "sub-polar point," but have employed in this connection a well-known phrase, "the sub-solar point," for which I can claim no authorship. See Young, "General Astronomy," 1898 edition; Muir, "Navigation," 1918, *et al.*

G. C. Comstock.

Washburn Observatory, University of Wisconsin, Madison, July

I regret that I inadvertently wrote "sub-polar" for "sub-solar" in my remarks on Prof. G. C. Comstock's book on Sumner lines, but this lapse makes no difference really to the statement that the proper description should be zenith point, and not sub-solar point (see p. vi of preface and pp. 2, 3, 5, etc.). Sub-solar refers to the sun only, and does not necessarily include sub-stellar or sub-lunar, but zenith point is common to all.

T. H. Tizard.

23 Geneva Road, Kingston-on-Thames, August 5.

The Research Department, Woolwich.[1]

By Sir Robert Robertson, K.B.E., F.R.S.

II.

Metallurgical Branch.

THE metallurgical branch of the Research Department had been established for some years before the war, the staff consisting of four metallurgists. As work increased, additions became imperative, and before the armistice the scientific staff numbered thirty-seven, of whom a number were women. At the end of 1916 the branch removed into a new building 120 ft. long and 55 ft. wide, divided into laboratories well equipped for mechanical testing of all kinds, chemical analysis, microscopy and photomicrography, experimental heat-treatment, the thermal study of alloys, and other branches of physical metallurgy. Figs. 4 and 5 show two of these laboratories. The machine shops of the Department, on which metallurgical work made great demands, were much extended and improved.

During the war the metallurgical branch was mainly occupied with a great variety of problems connected with the metallic materials of warlike stores used by the Navy, Army, and Air Force. The work was carried out in close association with the Ordnance Committee and other Departments concerned. It is possible to mention here only a very few of the specific problems attacked.

Before the war the manufacture of gun forgings was in the hands of a few armament firms of long experience, but with the great increase in output which took place from 1915 onwards a wider source of supply was drawn upon. The heat-treatment applied was not always the most suitable, and sometimes caused serious irregularity of properties throughout the forgings. Much was done to define the temperature limits appropriate to the different steels employed and to secure their application, thus eliminating those weaker tubes which were so frequently found among those which failed by stretching, choke, or expansion. The inspection tests were improved, especially in the determination of the yield point, a matter of great importance in a highly stressed structure such as a gun.

The extreme brittleness of some gun forgings put forward for test directed attention to the occurrence of "temper-brittleness" in nickel-chromium steel, and made investigation an urgent necessity. Slow cooling in the furnace after tempering was identified as the main cause of this form of brittleness, which is detected by the notched-bar impact test, and was accordingly forbidden by specification. Examination of samples representative of forgings in current supply made at the beginning of 1916 and at the end of 1918 showed that the notched-bar impact figure of the average nickel-chromium steel forging had very greatly improved, with no detriment to the other mechanical properties. The study of the notched-bar test was continued in association with the British Engineering Standards Committee, and much knowledge was gained as to its significance and conditions of application.

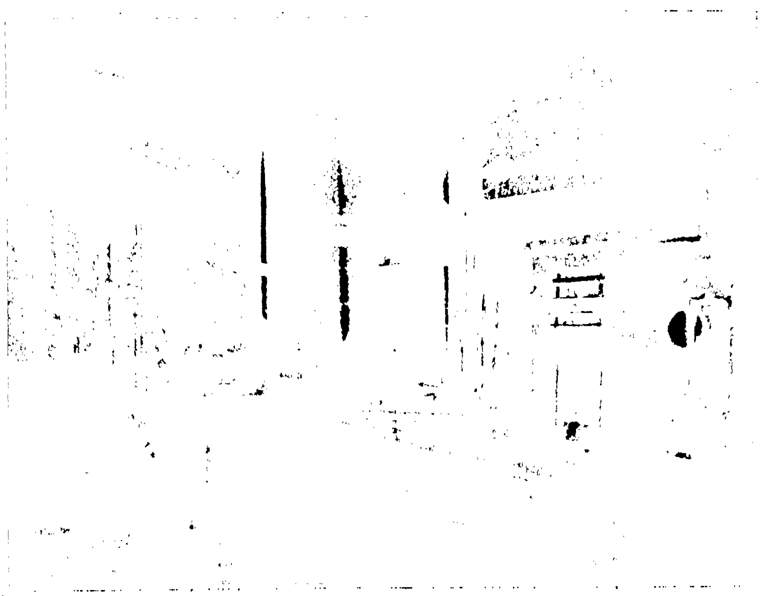

Fig. 4.—Portion of mechanical testing laboratory.

Much time has been given to the study of the elastic properties of steels and of the effect of overstrain and recovery, a subject of importance in connection with the strength of guns and their construction by methods involving the use of internal pressure.

Erosion, wear, and the development and extension of cracks in the bore have been studied in rifle and machine-gun barrels, as well as in guns. Many questions were solved in connection with the design and manufacture of bullet envelopes and the cores of armour-piercing bullets.

A method of applying the Brinell hardness test for the individual testing of H.E. shells which for one reason or another were in question as to their strength was developed, and resulted in the successful utilisation of very large numbers of shells which might otherwise have been rejected.

The numerous components of ammunition and

[1] Continued from p. 712.

fuzes were the subject of many investigations. As an example may be mentioned the hammer of the No. 106 fuze. This was liable to failure at a time of great output until the causes of difficulty were ascertained and sound methods of manufacture established. The introduction of a simple form of heat-treatment rendered possible the use of a rapid and economical stamping method which greatly assisted supply.

An investigation carried out upon brass small-arm cartridge cases gave very complete information connecting the behaviour of the case in the rifle with its properties, and especially with its hardness. The hardness is chiefly dependent on the degree of cold-work received in the final drawing operation, and manufacturers were assisted by information as to the requisite hardness at different parts of the case and the dimensions of the necessary tools for producing it. The measurements to ensure exact control of the hardness have been made possible by the use of a small machine designed in the Research Department shortly before the war for the determination of the hardness of very thin specimens. In this machine, which has proved useful in many unexpected ways, the Brinell test may be made on samples one-hundredth of an inch or even less in thickness, with balls as small as 0·8 mm. in diameter.

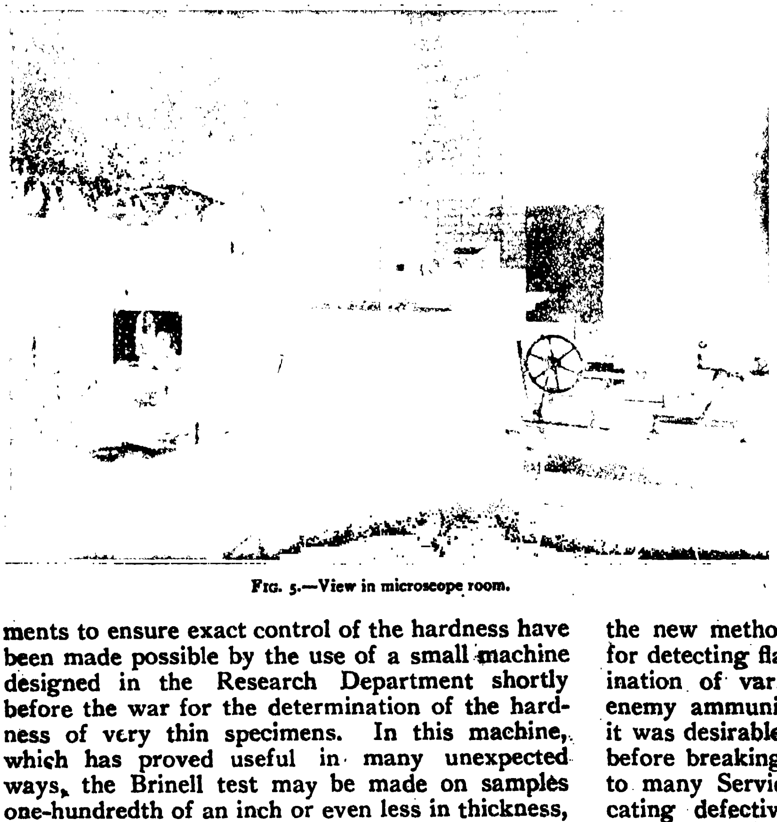

FIG. 5.—View in microscope room.

A thorough investigation of the phenomenon of "season-cracking" in brass and its prevention by low-temperature annealing has had a useful application in the removal of internal stress from cartridge cases.

Methods of casting brass ingots have been much improved. The long, narrow moulds formerly employed for ingots to be used in the manufacture of rod were productive of troublesome defects in the finished article.

The occurrence of the "extrusion defect," a central core of unsound material, in brass rod used for fuzes led to an extended study of the extrusion process, in which the flow of the hot brass is liable to form internal defects in a remarkable and characteristic way. A method of controlling the plastic flow to produce entirely sound rod has been devised.

The necessities of the war demanded that first consideration should be given to the solution of immediate practical problems. The use of substitutes and alternative methods of manufacture when supplies ran short, the easing of specifications to increase output with safety, the adaptation and introduction of inspection tests to meet changing conditions, the examination of enemy material, the tracing of causes of failure and the discovery and application of remedies, provided a large field for investigation. Work on the fundamental properties of metals and alloys, which is so necessary if research in applied metallurgy is to continue to be fruitful, was, however, continued throughout the war, and is now being further developed.

Radiological Branch.

In the beginning of 1916 the question of the penetration of metals by X-rays was first considered by the Research Department. After experiments with various types of apparatus under different conditions, it was found possible to penetrate a block of steel half an inch in thickness and show internal flaws. The Department at once realised the possibilities involved in this new use of X-rays as applied to Service requirements, and took steps with the best apparatus available to evolve a technique for applying the new method as widely as possible, not only for detecting flaws in steel, but also for the examination of various articles, such as unknown enemy ammunition, where for reasons of safety it was desirable to know the internal construction before breaking down. X-rays were also applied to many Service stores for the purpose of indicating defective assembly, and for discovering faults such as blow-holes and internal flaws in metals.

As research progressed it became apparent that in order to obtain the best results the whole subject of radiology needed careful study so that its methods might be modified and adapted to this new use. More powerful tubes and high-power electrical machinery were essential, and the photographic side of the subject required special treatment. A general scheme of research on the subject of radiology as applied to the examination of Service materials was consequently undertaken,

and this included the construction, in the Department, of special apparatus and high-tension electrical machinery; research was also undertaken on such associated subjects as the detection of feeble radiation and the measurement of its intensity.

Certain progress has been made, with the result that X-rays are being used to a much greater extent as research proceeds. X-ray examination of welds is the only method by which their soundness can be demonstrated, and it is now possible to penetrate more than 2½ in. of steel to show internal flaws. Fig. 6 shows part of one installation in the Research Department for the examination of materials.

Proof and Experimental Branch.

All guns are tested to a pressure in excess of their working pressures, and the ballistics of all lots of propellants are ascertained, by firing into sand butts. Carriages, recuperators, and many small stores are also similarly proved before acceptance.

Velocities are measured by means of Boulangé chronographs, and pressures by means of copper crushers in piston gauges. Flat-headed shot are used, to keep the penetration into the sand butts as low as possible.

Experimental firing, which principally consists in the determination of the weights of propellant necessary to give specified ballistics under various conditions, is also undertaken, and for this purpose the proof butts staff work in collaboration with the internal ballistic branch, by which the preliminary calculations are made.

Considerable expansion of *personnel* and *matériel* was necessary during the war to cope with the vast amount of proof and experiments. At the armistice the staff had increased to nearly ten times its pre-war figure, and included a number of women, who were most efficiently performing their trying duties on the firing batteries.

Internal Ballistic Branch.

Starting with a staff of two in the early part of the war, the branch numbered at the armistice more than twenty members, who dealt with all problems relating to the internal ballistics of propellants and the internal design of guns for all the Services. Newer and more powerful apparatus has been devised for determining the burning characteristics of explosives, and a great improvement has taken place in methods of analysing data. This is especially noticeable as regards the ballistic design of ordnance. The old system of calculation in use prior to the war was based on trial and error, and involved a series of laborious and lengthy operations. It had the added disadvantage of restricting the calculator to working out this result with one definite set of initial conditions only, and consequently no certain predictions could be made as to whether the best combination of charge weight, propellant size, chamber capacity, etc., had been employed.

It was thus frequently found that the finished gun was not suitable for the original purpose in view. Research into the thermodynamical properties of propellants led to the construction of a more accurate theory on which to base design, and, apart from the economy effected in the labour of calculation, it became possible to select with considerable accuracy the best and most economical combination for any ballistic requirements. Also by an application of the calculus of variations the calculator is now enabled to predict with considerable accuracy the probable deviation in the ballistics from round to round, a valuable criterion of the practical utility of a design.

The application of this new theory effected considerable changes in design. For example, it was found that large reductions could be effected in the chamber capacities of several guns, with

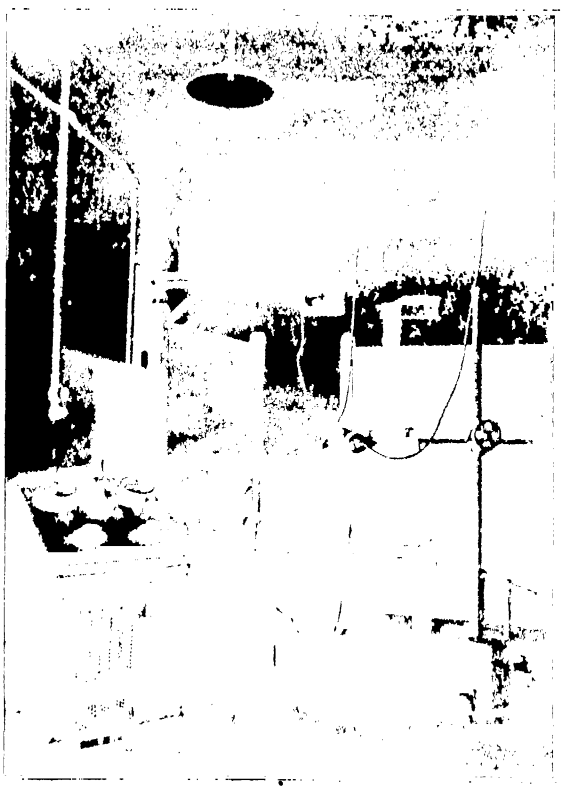

Fig. 6.—Portion of radiological laboratory.

corresponding reductions in the charge weights, without affecting the ballistics. This modification had the result of materially increasing the life of the guns, and the reduction in charge weight effected an appreciable economy in the financial cost of each round, a serious consideration in view of the magnitude of the scale on which operations were conducted.

Since the armistice the ballistic branch has been to a large extent occupied in digesting and interpreting the data amassed during the war, the results being published in the form of R.D. Reports.

A programme has been drawn up for future research, and good progress is being made in all branches of the science and its applications.

The Romance of Bird Life.

MR. ARTHUR BROOK has made a welcome addition to the "British Birds" Photographic Series; he deals skilfully with the buzzard at home, and gives us twelve fine pictures.[1] During the last three or four years the buzzard has increased markedly in central Wales. It builds upon trees and in cliffs, or even amongst heather and rushes, and an inaccessible nest is the exception rather than the rule. The one studied by Mr. Brook was on a cliff, where with some difficulty a hiding-place was built for the observer. There were two young birds about a week old, and when observations began the nest contained several mice, one frog, one mole, half a dozen castings, and a quantity of fresh leaves of the mountain ash. The cock did all the hunting, usually bringing his booty to the hen, who sat on a knoll near the nest. She carried the food to the young ones in her beak or talons. Occasionally the cock brought the food to the nest himself. The hen decorated the nest daily with fresh leaves, and she also brought tufts of mountain grass on which the young ones cleaned their beaks. One day the booty included four young wild ducks, about two days old, and one of these was swallowed whole If food is scarce the stronger of the two young buzzards will kill its weaker companion. The observer saw the young birds practising flight and playing with the food. He captured one that flew off too soon, and replaced it in the nest, whence in the afternoon of the same day it took wing successfully. The buzzard is said to be a coward, but when the cock bird discovered Mr. Brook leaving the "hide" it showed great courage, making disconcerting swoops at a high velocity, and following him closely for quite two miles.

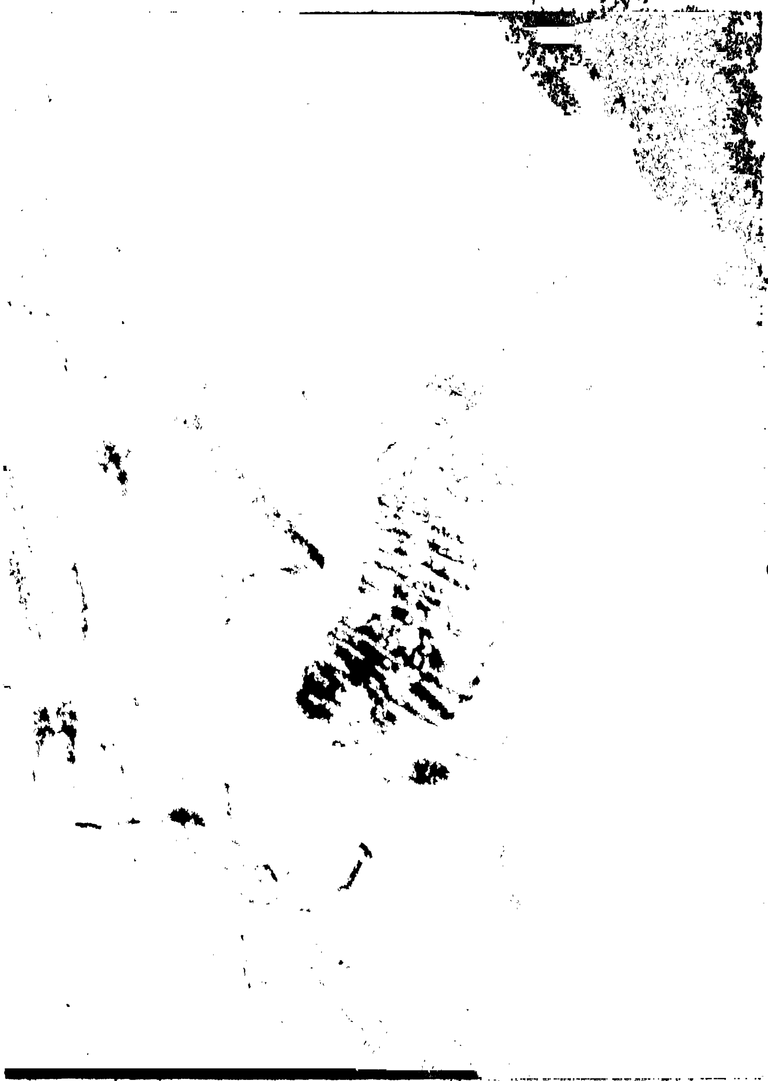

FIG. 1—The hen buzzard alighting at the nest From "The Buzzard at Home."

With an inexpensive little Kodak, and often in bad weather conditions, Miss Hilda Terras has managed to give us a score of very presentable and interesting pictures of various events in the history of a cuckoo's egg in a hedge-sparrow's nest.[2] She had this good luck, however, that the cuckoo was obliging enough to put the egg in question into a nest almost on the doorstep of the observer's home. Only a true amateur—we use the word very discriminatingly—could have such luck. The hedge-sparrow made for the prospecting cuckoo like a little demon; nesting birds have a highly developed sense of "territory," or is there more—of homestead? The cuckoo persisted; there was a cessation of hostilities; at an urgent moment circumstances were opportune; the cuckoo flew on to the hedge about 2 ft. from the nest, and looked about in a nervous, cunning way. "I could almost swear it was saying to itself anxiously, 'Are they looking? No—thank goodness, I've done them at *last*.' And then, without any hesitation, it hopped straight into the hedge and disappeared from view. For about

[1] "The Buzzard at Home." By Arthur Brook ("British Birds" Photographic Series.) Pp 15+12 plates. (London, Witherby and Co., 1920.) Price 3s. 6d net

[2] "The Story of a Cuckoo's Egg." Told and pictured by Hilda Terras. Pp. 95. (London: The Swarthmore Press, Ltd., n.d.) Price 6s. net.

a minute it was there; then it came out and flew away. Burning with curiosity, I hurried into the garden, and, eagerly parting the branches of the hedge, looked into the nest—and lo and behold, there, lying in Henrietta's dear little cup-shaped, softly lined cradle, I saw the cuckoo's egg! One of my sisters had watched the whole affair with me, and once more we were amazed at the positively uncanny sagacity of the bird. The whole thing seemed so extraordinarily intelligent and so *mean*."

The observer noticed that the cuckoo had not her egg in her bill, and concluded that it was in its mouth out of sight. But might not the cuckoo lay the egg in the nest? The hedge-sparrow laid four eggs, and when the young cuckoo was hatched the usual tragedy occurred. "For the first two days his shiny naked little body was dark fawny-pink in colour, but by the fourth day he had gone almost black, and his eyes, covered over with blue-black skin, looked disproportionately large. From the moment that his eyes opened he showed signs of surprising viciousness whenever I put my hand anywhere near the nest." When the young cuckoo was a fortnight old, more than filling the nest, the foster-mother was seen brooding, "uncomfortably crouched on top of his broad and ample back. It was rather like a pigeon trying to brood a hen." Whenever either of the foster-parents approached, the young cuckoo made a "strange little tinkling noise, . . . just like a tiny tinkling silver bell." The menu consisted of grubs, daddy-long-legs, butterflies, caterpillars, and small insects, and the number collected and consumed in a day was amazing. The indefatigable foster-parents continued to feed the cuckoo for more than a week after it had left the nest.

Miss Terras tells her story in a very attractive way. We do not know whether she has done this by instinct or by art, but we know we have

FIG. 2.—Hedge-sparrow feeding a young cuckoo. From "The Story of a Cuckoo's Egg."

had a most delightful hour. We recommend the book very strongly to young people and to those who would renew their youth.

Helium: Its Production and Uses.[1]

By PROF. J. C. MCLENNAN, F.R.S.

IN 1868 Janssen (*Compt. rend.*, 1868, vol. lxvii., p. 838) directed attention to the existence of certain lines hitherto unobserved in the solar spectrum, which we now know are given by the element helium. In the same year Frankland and Lockyer[2] (Proc. Roy. Soc., 1868, vol. xvii., p. 91), from their observations on these spectral lines, were led to announce the existence of an element in the sun which up to that time had not been found on the earth. To this element they gave the name "helium."

In 1882 the discovery was made by Palmieri (*Gazzetta*, 1882, vol. xii., p. 556) that the helium spectrum could be obtained from rocks and lavas taken from Vesuvius.

In the United States of America, Hillebrand in 1890 (Bull. U.S. Geol. Survey, 1890, No. 78, p. 43) succeeded in obtaining a quantity of gas

1 From a lecture delivered before the Chemical Society on June 17.
2 See NATURE for May 20, p. 361.

from the mineral uraninite, which from chemical and spectroscopic tests he concluded was nitrogen. This gas, we now know, was, in fact, helium.

Finally, in 1895, Sir William Ramsay (*Chem. News*, 1895, vol. lxxi., p. 151) discovered that a gas could be obtained from the mineral cleveite. This gas he purified, and, on examining its spectrum, he found it to be the long-sought-for element helium. From 1895 up to the present, investigation has shown that helium is widely diffused throughout the earth. It can be obtained from many types of rocks, minerals, and earths, and it is present in varying amounts in practically all natural gases and spring waters. It is present, too, in the atmosphere of the earth to the extent of about four parts in one million by volume.

The gases from some springs in France have been shown to contain as much as 5 per cent. of helium. In the Western States of America, especially in Texas, natural gases exist which contain from 1 to 2 per cent. of helium, but within the British Empire no natural gases which have been examined show a helium content as high as 0·5 per cent.

Until the spring of 1918 not more than 3 or 4 cubic metres of helium had, in the aggregate, been collected, and its market price, though variable, was about 300*l.* per cubic foot.

The principal characteristics of helium are:

(1) Its extreme lightness. It is only twice as heavy as hydrogen, the lightest element as yet isolated.

(2) Its absolute inertness. All attempts to effect combinations of helium and the rare gases, neon, argon, krypton, and xenon, as well, with other elements have as yet failed.

(3) Its close approximation to an ideal or perfect gas. It is monatomic, and is liquefiable at a temperature below that of liquid hydrogen. By causing liquid helium to evaporate in a vacuum, Onnes (Proc. K. Akad. Wetensch. Amsterdam, 1915, vol. xviii., p. 493) has succeeded in reaching a temperature within 1° or 2° of the absolute zero.

(4) Its low sparking potential. Electric discharges can be passed through helium more easily than through most other gases.

No element has had a more romantic history than helium, and none is of greater interest to men of science than is this gas at the present time. Its formation as a disintegration product of the radio-active elements, and the identity of the nuclei of helium atoms with α-rays, give it a unique position among the elements.

Intense interest has been aroused by Sir Ernest Rutherford's recent discovery that in the nuclei of helium atoms in the form of α-rays we have a powerful and effective agent for disintegrating and simplifying the nuclei of atoms generally. This discovery points the way to still further progress. In the past helium has been considered a rare and precious gas. To-day it is being produced in large quantities, and in view of the proposal now being put forward to use this gas in place of hydrogen as a filling for airships, one is apt to consider it to be not so precious as heretofore. It may be, however, that such vast and vitally important directions will suddenly be opened up in which helium can be utilised that the conservation of the gas, while it is still available to us, will become a matter of the first importance.

Shortly after the commencement of the war in 1914, it became evident that if helium were available in sufficient quantities to replace hydrogen in naval and military airships, losses in life and equipment would be very greatly lessened.

The fact that helium is both non-inflammable and non-explosive, and possesses 92 per cent. of the lifting power of hydrogen, makes it a most suitable filling for airship envelopes. By the use of helium the engines of airships can be placed within the envelope if desired. A further advantage possessed by helium over hydrogen is that the buoyancy may be increased or decreased at will by heating or cooling the gas by electric or other means, which fact may possibly lead to considerable modifications in the technique of airship manœuvring and navigation. Moreover, the loss of gas from diffusion through the envelope is less with helium than with hydrogen to the extent of about 30 per cent.

Although there are indications that proposals had been put forward during the war by men of science in Allied and enemy countries, as well as in the British Empire, regarding the development of supplies of helium for aeronautical purposes, it should be stated that the movement that led up to the investigation which it was my privilege to undertake was initiated by Sir Richard Threlfall. The existence in America of supplies of natural gas containing helium in varying amounts was known to him and others, and preliminary calculations as to the cost of production, transportation, etc., which he made led him to believe that there was substantial ground for thinking that helium could be obtained in large quantities at a cost which would not be prohibitive.

Sir Richard's proposals were laid before the Board of Invention and Research of the British Admiralty, and in the autumn of 1915 the author was asked by that Board to determine the helium content of the supplies of natural gas in Canada, and later on of those within the Empire, to carry out a series of experiments on a semi-commercial scale with the helium supplies which were available, and also to work out all technical details in connection with the production of helium in quantity, as well as those relating to the re-purification, on a large scale, of such supplies as might be delivered and become contaminated with air in service. The present paper aims at giving a brief account of this investigation.

Composition of the Natural Gases Investigated.

In commencing the investigation, a survey was made of all the natural gases available in larger or smaller quantities within the Empire with the view of ascertaining their helium content. Natural gases from Ontario and Alberta, Canada, were found to be the richest in helium, and these

sources, it was found, could supply from 10,000,000 to 12,000,000 cubic feet of helium per year. The following is a summary of the results obtained from the analyses of a number of the gases investigated. They include, it will be seen, a few samples from outside the Empire. For a complete account of this part of the investigation, the reader is referred to Bulletin No. 31 of the Mines Branch, Department of Mines, Canada, 1920.

(a) *Ontario Gases.*—The analysis made by Profs. Ellis, Bain, and Ardagh (Report of Bureau of Mines of Ontario, 1914) of the natural gases supplied to the experimental station, initially set up at Hamilton, Ontario (Blackheath System), is as follows:—

Methane	80 per cent.
Ethane	12 „
Nitrogen	8 „

It was found, however, on operating with this gas that the percentage assigned to methane really included a considerable proportion of gasoline, pentane, and butane as well. The helium content of the gas was found to be 0·34 per cent.

(b) *Alberta Gases.*—Gas taken from the mains leading from the Bow Island supply to Calgary was found to be quite free from the heavier hydrocarbons. At times it contained slight amounts of water vapour and occasionally a trace of carbon dioxide as well. Its approximate composition is given under I.

	I.	II.
Helium	0·33 per cent.	0·36 per cent.
Methane	87·6 „	91·6 „
Ethane	0·9 „	1·9 „
Nitrogen	11·2 „	6·14 „
Carbon dioxide	trace	trace
Water vapour	trace	trace

One well in particular, namely, No. 25 Barnwell, which has recently been driven, and now supplies gas to the system, was found to have a product of the composition II.

(c) *New Brunswick Gases.*—Some natural gases obtained from wells struck near Moncton, New Brunswick, Canada, were examined, and found to have the following composition:

Methane	80·0 per cent.
Ethane	7·2 „
Carbon dioxide	None
Oxygen	None
Nitrogen	12·8 per cent.
Helium	0·064 „

(d) *New Zealand Gases.*—A series of samples of the natural gases from the Hanmer, Kotuka, Weber, Blairlogie, and Rotorua supplies in New Zealand was forwarded by Mr. J. S. McLaurin, Dominion Analyst of Wellington, New Zealand, for examination, but was found to have an insignificant helium content, the richest containing not more than 0·077 per cent.

(e) *Italian Gases. Pisa.*—A sample of the natural gas brought by pipe to the city of Pisa, in Italy, was examined, and found to have the following composition:

Methane	80·0 per cent.
Ethane	4·0 „
Carbon dioxide	3·5 „
Nitrogen	11·9 „
Oxygen	0·6 „
Helium	None

(f) *Miscellaneous Analyses.*—An analysis of the natural gas supply from Heathfield, Sussex, England, showed it to have a helium content of but 0·21 per cent. The gas from the King Spring, Bath, England, was found to contain 0·16 per cent. of helium, and analyses of natural gases obtained from Trinidad and from Peru showed their helium content to be negligible. An interesting observation was made in connection with natural gases obtained from Pitt Meadows, Fraser River Valley, and Pender Island, in the Gulf of Georgia, British Columbia. Both these gases were found to have a nitrogen content of more than 99 per cent.

Preliminary Experiments.

Soon after taking up the investigation, it was found, as mentioned above, that large supplies of helium were available in the natural gas fields of Southern Alberta, and that a small supply could be obtained from a gas field situated about twenty-five miles to the south-west of the city of Hamilton, in Ontario. In 1917 the Board of Invention and Research decided to endeavour to exploit these sources of supply, and operations were begun by setting up, as already stated, a small experimental station near the city of Hamilton.

At this station efforts were directed towards constructing a machine which would efficiently and economically separate out the helium from the other constituents present in the natural gas. The carrying out of this work expeditiously was made possible through the hearty co-operation of L'Air Liquide Société of Paris and Toronto, which generously lent, free of cost, a Claude oxygen column and the necessary auxiliary liquefying equipment for the investigation.

By making suitable additions to, and modifications in, this oxygen rectifying column, it was ascertained that the problem of separating, on a commercial scale, the helium which was present in this crude gas to the extent of only 0·33 per cent. was one capable of satisfactory solution. Early in 1918 it was found possible to raise the percentage of helium in the gas to 5·0 by passing it through the special rectifying column once only, and as the gas obtained in this way consisted of nitrogen and helium with a small percentage of methane, it became therefore a comparatively simple matter to obtain helium of a high degree of purity. In one particular set of experiments on this final rectification, helium of 87 per cent. purity was obtained.

Experimental Station at Calgary, Alberta.

In order to operate on the natural gas of the Bow Island system in Southern Alberta, an experi-

mental station was established at Calgary in the autumn of 1918, and, starting with the knowledge acquired through the preliminary operations at Hamilton, rapid progress was made in developing a rectification and purifying column, together with the requisite auxiliary equipment, which would efficiently and cheaply separate the helium from the natural gas.

Development of the Rectification Column.

In proceeding to develop an equipment for separating the helium from the other constituents of natural gas, three lines of attack appeared to be open, namely, (*a*) by producing the refrigeration necessary to liquefy all the gases except the helium by the cold obtainable from the natural gas itself, (*b*) by using external refrigeration entirely, such as that obtainable with ammonia, carbon dioxide, liquid air, liquid nitrogen, etc., and (*c*) by combining methods (*a*) and (*b*).

The last method had been successfully used for the production of helium by the naval authorities of the United States in the Texas field, but from the information supplied it did not appear that this process could be considered to be an economical one.

The preliminary experiments at Hamilton, Ontario, made it abundantly clear that method (*a*) was very promising and likely to be both efficient and economical. This method was therefore adopted. It was evident from the start that to produce an efficient method the main difficulty to overcome would be the securing of a proper balance between the heat exchangers, the liquefier, the vaporisers, and the rectification portions of the machine. A machine was therefore designed, constructed, and supplied with piping which possessed great flexibility, and, in its general scheme, followed the lines of the Claude oxygen-producing column. It is unnecessary to go into details regarding the operation of this machine. It will suffice to say that it was tested under a variety of conditions. Notes were taken of the temperatures reached at different points in the machine under equilibrium conditions when the gas was passed through it in various ways. As a result of this procedure, it was soon found what parts of the machine could be eliminated and what parts could be modified with advantage. When those changes were made which seemed desirable in the light of the experience gained, it was found that a machine had been evolved which would give highly satisfactory results.

In operating with this machine, it was found that helium of 87 to 90 per cent. purity could be regularly and continuously produced.

Operations.

The experimental machine just described was used continuously for a series of trial runs from December 1, 1919, to April 17, 1920. In making a run, about 500,000 cubic feet were passed through the machine, and from this amount upwards of 20,000 cubic feet of the gas, containing 5 to 6 per cent. of helium, were obtained. As this low-grade product was made it was stored in a large balloon, and the residual gas was passed back into the mains for use in the city of Calgary. The 5 to 6 per cent. product was compressed to from 20 to 30 atmospheres, and then passed through vaporisers. The amount of final product, of 87 to 90 per cent. purity, obtained in each run rose steadily in the course of the operations from about 300 cubic feet to more than 700 cubic feet per run. From this it will be seen that the efficiency obtained with each of the two operations was about 67 per cent. In special runs made under exceptionally good conditions a still higher efficiency was obtained. One of the curves given in Fig. 1 shows that the purity of the high-grade final product was steadily maintained in the series

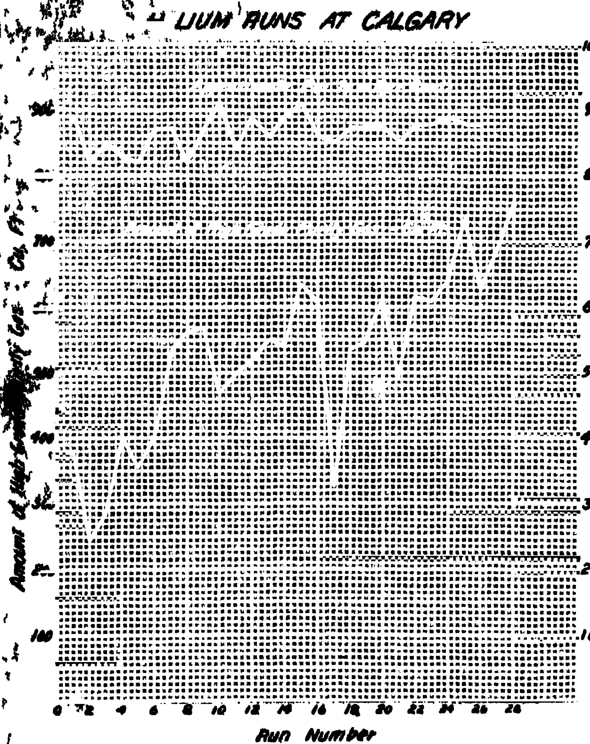

FIG. 1.

of runs, and the other curve exhibits the steady increase made in the production of helium of high-grade purity.

High-grade Purification.

When it was seen that the highest purity obtainable with the experimental machine under actual running conditions was about 90 per cent., steps were taken to design and construct an auxiliary piece of apparatus for raising the purity of the gas up to 99 per cent. or higher. This apparatus as constructed could be used, not only for obtaining a product of high purity at the works, but also for purifying helium which became contaminated with air by use in balloons in service. Through numerous delays experienced in obtaining delivery of tubing, liquefying equipment, etc.,

this purifying apparatus has not been given any more than a preliminary trial. From this, however, it is quite evident that it will prove satisfactory in operation. For the purpose of carrying out this scheme of high-grade purification, a liquid-air plant was installed by the University of Toronto. Motors and an electric current supply were furnished by the Hydro-Electric Commission of Ontario, and a special financial grant was made by the Honorary Advisory Council for Scientific and Industrial Research of Canada to supplement that made by the Admiralty and the Air Board of Great Britain.

Final Design of Helium-extracting Apparatus.

Every step in the production of high-grade helium has been carefully examined and tested. From the experience gained, we have been able to draw up specifications for a commercial plant which will enable one to treat the whole of the natural gas of the Bow Island supply in Alberta. The unit proposed will deal with about 1600 cubic metres or 56,500 cubic feet of gas per hour at normal pressure and temperature. At the altitude of Calgary, this would be equivalent to 62,400 cubic feet per hour. The machine would easily cope with 66,000 cubic feet per hour or 1100 cubic feet per minute. Of these machines, six would deal with 9,500,000 cubic feet of gas per day, and would thus take about the average daily supply available from the field, as based on records of the average yearly consumption. In order to have sufficient machines to operate regularly to capacity, it would probably be advisable to have eight helium columns included in the plant.

The cost of a commercial plant suitable for treating the whole of the supply of the Alberta field would probably be less than 150,000*l*. The amount of helium of upwards of 97 per cent. purity obtainable per year from the field would be about 10,500,000 cubic feet. This is based on the assumption of an efficiency of 80 per cent., which experience has shown is obtainable. As to operating costs, our experience has shown that, allowing for interest on the investment, a ten years' amortisation, salaries, supplies, and running charges, helium can be produced at the Alberta field for considerably less than 10*l*. per 1000 cubic feet. This sum does not, of course, include the cost of purchasing cylinders or of transporting them from and to the works. Neither does it include any compensation to the owners of the field for the supply of gas.

(To be continued.)

Obituary.

PROF. JOHN PERRY, F.R.S.

THE death of Prof. John Perry on August 4, at the age of seventy, leaves a blank in our scientific circle which cannot well be filled. A man of original mind and original manner, a warm-hearted Protestant Irishman, impulsive and enthusiastic in whatever cause he might engage, simple-minded to a degree and a thorough-going optimist, one of the most delightful of companions, he was of the class of lovable men and popular accordingly; he will be much missed, particularly at meetings of the British Association, of which he had been the general treasurer of late years.

Perry was educated in Belfast, finally at Queen's College, where he came under Andrews, one of the ablest and most original men of his day; it was from Andrews that he imbibed his feeling for chemistry, unusual in the engineer and mathematician: at least, he learnt to appreciate the part played by the electrolyte in chemical interchanges—as he once told me, through having fused out the bottom of Andrews's platinum crucible by heating potash in it. Later he was an assistant to William Thomson (Lord Kelvin). Under the influence of two such men his genius could not but unfold.

Perry began his career at Clifton College. I first met him at Clifton at a dinner, where, of course, he out-talked everyone: I can well recollect how he amused us and how he called Sir Walter Scott an upholsterer. He was always a voracious novel-reader and remembered what he had read in an extraordinary way. On the occasion of the British Association visit to Winnipeg, he often astonished his travelling companions by his local knowledge, as he identified spot after spot with Fenimore Cooper's characters.

From Clifton, Perry went to Glasgow to assist Thomson, I imagine on Andrews's recommendation. In 1875 he went to Japan and was one of the band who gave the Japanese their first lessons in science—to be cast off when done with; like Ayrton and Divers, however, he was an ultra-enthusiastic Japanophile. In Japan he became associated with Ayrton and a constant flow of communications, mainly on electrical subjects, to the Royal and other societies was the consequence of the partnership. In those days what Ayrton and Perry did not know or do or claim to have done was not worth knowing, doing or claiming; no two men, in the exuberance of their youth, were ever better satisfied with themselves. They were in remarkable contrast: entirely diverse yet complementary natures, each cognisant and respectful of the other's special ability. Ayrton was the worldly, practical member of the firm, Perry the dreamer. Ayrton always had a sense of what was wanted and what would pay: he, I believe, usually set the problem; Perry worked out a solution, which Ayrton then criticised and referred back to Perry for development. In the same manner, I believe, he cooperated, during the war, with the mechanical genius of Sidney Brown—the husband of his niece—in the development of the gyrostatic compass.

The partnership with Ayrton was continued several years after their return to England in 1879. They were in the van of electrical progress, in some respects before their time—as in the case of Telpherage, which they developed in association with Fleeming Jenkin. Those were wonderful days: we were just learning to know and use electricity. A little later, Perry's house was often the scene of most stimulating debates, especially when Larmor and Lodge forgathered there with Fitzgerald, whom Perry adored.

Perry's best work was done at the Finsbury Technical College. Ayrton and I were called on to lay the foundations of the work of the City and Guilds Institute for the Advancement of Technical Education in October, 1879; we began in temporary quarters in Cowper Street, Finsbury. I found not only that plans were prepared for a separate chemical laboratory but also that steps had already been taken towards the erection of the building. I took exception to the scheme on the ground that more than a mere knowledge of chemistry would be required of the technical chemist of the future: that he must know something of the fundamentals of mathematics, of physics—especially electricity—and of engineering—drawing in particular. My view prevailed and we set to work to excogitate a practical programme and design a building. In 1871 we roped in Perry to our aid: our trio always fought like thieves over every detail but remained as one man throughout. The outcome was the present Finsbury Technical College and the original Finsbury scheme: I say "original" because our successors were never whole-hearted followers of our convictions and aspirations. This much I may assert as the last of the Finsbury Mohicans—we were in advance of our time and our fate has been the usual fate of pioneers and prophets. We cut the college adrift from all external examinations. We imposed an entrance examination on applicants. Not only was the course comprehensive but also the methods were special, practical and advisedly educative rather than informative; our students were young and their period of training was short but at its close, although they did not know a great deal, they had learnt to think for themselves and to do by themselves, so that they were mentally prepared to continue learning when left to their own devices. Now the college is to experience the fate of our scheme; it is said that it will be closed next year. When established it was the most original school in the country and it has been a remarkable success. We are a strange people: we seem never to know when we have hold of a good thing and cannot long maintain a consistent policy. In abandoning Finsbury the City and Guilds Institute signs its own death-warrant; but it has long been practically defunct, the men of imagination and outlook who founded it having bred no successors.

Perry did not leave Finsbury until 1896, when he became professor of mathematics and mechanics in the Royal College of Science, South Kensington. He had the advantage of being a practical engineer by training; this, added to his mathematical genius and his intimate knowledge of electrical science, not forgetting his literary proclivities, made him a man of unusual breadth and sanity of outlook. No special scientific achievement is to be associated with his name; his real interest lay in the work of education and he will go down to fame as an original and constructive teacher who laid the foundation of a new era. He made mathematical teaching practical and taught many who could never have mastered the abstract subject to use such knowledge and ability as they had with effect. As examiner in mathematics to the Science and Art Department he exercised a wide and beneficent influence on the teaching of this subject. His methods were not everywhere popular, but this was mainly because of the special demands their practice made on the intelligence of the teacher. As he more than once remarked to me, few really understood him. Still, the written word remains: Perry has left much on record which will be of service to a future, more appreciative generation.

H. E. A.

PROF. PERRY'S love of research and restless spirit of inquiry have inspired the lives of innumerable students who came under his influence. Who can measure what the nation owes to Perry for the intellectual gifts he distributed so freely to so many men? Who can measure the boundaries to which his influence will reach through the lives and activities of his students? The man who inspires is in time forgotten, but those whom he stimulates inspire others, so that his influence increases as time goes on. An engineering work like a fine bridge can be seen of all, and the builder is applauded and rewarded. The scientific spirit is apprehended by few, and those who possess it and spend their lives in the true service of the nation by cherishing it and by passing it on to others are unknown and unrewarded by authority, but are held in respect and affection by those who receive from them what so few are able to give. Perry gave lavishly, and his students responded with enthusiastic affection. He ranged wide in the regions of science. In Japan he and his friend and colleague Ayrton experimented furiously. Paper after paper came red-hot from their intellectual forge until even Lord Kelvin said that the pole of scientific research had shifted to Japan.

Finsbury Technical College was founded to do something in technical education which had not been done before. Perry and his colleagues, Ayrton and Armstrong, launched the college. They made it a pioneer in technical education. They made it world-famous. Everything which these men did was new, unorthodox, stimulating, and vastly interesting to the keen young men who flocked from the workshop to the college to hear and often to help them. Perry was unorthodox of the unorthodox. He taught his students to mistrust authority and to try things out for themselves.

Perry will probably be chiefly remembered by engineers as the man who broke through the formal defences of mathematics and taught them mathematics through what they knew of machinery. His book on "Practical Mathematics," originating in his Finsbury course, has been translated into many languages, and many generations in many lands will therefore benefit from Perry's determination to teach his own students the fundamental truths of mathematics so well that they could use their knowledge as easily as they could use their mother tongue.

Perry continued his work as professor of mathematics and mechanics at the Royal College of Science, leaving Finsbury in 1896. In those days the professors at the Finsbury Technical College were expected to run an arduous day course, and in addition an evening course as well. His relief at the escape from this double duty was great. In more recent years he guided the fortunes of the British Association for the Advancement of Science as its general treasurer. Perry has done a great work, and his work will live after him.

W. E. D.

PROF. AUGUSTO RIGHI, FOR.MEM. R.S.

PROF. AUGUSTO RIGHI, who died suddenly on June 8 at seventy years of age, is said to have been appointed assistant to the professor of physics in the University of Bologna—his native city—at the age of twenty-one. In 1877 he was *Libero Docente,* and in 1880 was appointed ordinary professor at Padua, whence after a few years he returned to Bologna as head of the physics department.

Righi was a skilled experimenter and an industrious worker. His original investigations lay chiefly in the domain of electricity, magnetism, and light. One of his discoveries was the variation of the resistance of bismuth in a magnetic field, a phenomenon on which an instrument for measuring the intensity of a field has been based. He was led to this discovery by an examination of the Hall effect in different metals in the year 1883. His results were published in the *Journal de Physique* (2), 1883, p. 512, and in the *Comptes rendus,* vol. xcvii., p. 672, as well as in Italian; most fully in Bologna Acad. Sci. Mem., vol. v., 1883, pp. 103–26. An abstract was given in NATURE, vol. xxx., p. 569.

Righi's earliest papers appeared in 1873, and dealt with a variety of topics, many of them connected with electrostatic problems and voltaic electricity. One of the subjects on which at one time he laid stress was the dilatation of the glass or quartz of a Leyden jar, and of insulators in general, under electric stress—what he called "galvanic dilatation": see, for instance, *Comptes rendus,* vol. lxxxviii., 1879, p. 1262. He also examined the changes of length due to magnetisation, and discussed the phenomena of permanent steel magnets. About 1880 Righi began a long series of researches on electric discharge *in vacuo* and in air, and pursued the subject in various forms to the end of his life. He was much interested in photo-electric effects, and contributed some new facts to the discharge of electrified bodies by ultra-violet light. He failed to discover electrons, but he knew that carriers of negative electricity were liberated, and took steps to observe their trajectory in a magnetic field, thus exhibiting the phenomenon as a variety of cathode rays. He also found that the discharge could be stopped by an electric charge of inverse sign, constant in density for a given metal.

Righi was keenly interested in the work of Hertz, and corresponded with the present writer on the subject of electric waves. A special form of Hertz oscillator, known as Righi's pattern, consisting of a couple of spheres with adjacent faces immersed in oil and charged at the back from two other spheres, was used by some people, and is depicted as a form appropriate to wireless telegraphy in Mr. Marconi's first patent, though the connection of the outer spheres to an elevated plate and to ground respectively—a plan efficiently introduced by Mr. Marconi for practical purposes—really converted the spherical oscillator into nothing but a series of spark gaps. It is understood that Mr. Marconi had visited Righi's laboratory and seen his experiments on Hertzian waves, but was not one of his students. Righi, in his correspondence, frequently expressed surprise at the novelty attributed to the invention in its very early days by Sir William Preece and other English officials.

In the Memoirs of the Academy of Sciences of the Institute of Bologna, Righi expounded many of the new discoveries as they were being made in physics—among others an excellent and semi-mathematical exposition of the Zeeman phenomenon (see vol. viii., ser. 5, pp. 59–90, December, 1899). He also wrote on the equations of Hertz and their solution, in vol. ix. of the Memoirs of the same Academy, pp. 3–28 (February, 1901); and, again, on the electromagnetic mass of electrons in vol. iii., ser. 6, pp. 71–84 (February, 1906). These papers show that though chiefly an experimental physicist, he had a sound grasp of general theory, and must have had considerable influence in making known the work of British and other physicists to his countrymen. A memoir on the theory of relativity was contributed by Righi to the Institute of Bologna so recently as April 18 last (vol. vii., ser. 7, pp. 70–82).

An experimental paper of Righi's on the possible existence of magnetic rays, dated May 17, 1908, vol. v., ser. 6, of the same Memoirs, pp. 95–150, deserves mention, because of the cathode ray inquiry there described and the speculation based upon it. The subject is continued in vol. vi., pp. 45–64, and in vol. x., pp. 79–103, also in vol. i., ser. 7, pp. 3–36, where results are described for many different gases. It is taken up again, after a discussion of the paths of electrons in magnetic fields, in vol. ii., ser. 7, pp. 11–41.

Righi describes further experiments in vol. iii.,

pp. 23–42, and he has a paper on ionisation in a magnetic field in vol. iv., ser. 7, pp. 27–44. His chief work, in which he summarises these and other results, is entitled "I fenomeni elettro-atomici sotto l'azione del magnetismo," a work which met with a very cordial reception among Italian physicists, who must, indeed, have been indebted to Righi's activity and clearness of exposition for much of their knowledge of contemporary physics.

Students adequately familiar with Italian—as the writer cannot claim to be—speak of Righi's writings as marked by extraordinary clearness and simplicity of style, so that they can be read by people of average culture, at least in their non-mathematical portions.

Numerous honours were conferred upon Righi, among others a 10,000 lira prize of the Accàdemia dei Lincei, and the Hughes medal of the Royal Society. The Royal Society also selected him as a foreign member, and he succeeded Lord Kelvin as foreign member of the Royal Academy of Sciences at Upsala. In 1905 he was elected a Senator of the Italian Parliament.

By Righi's death Italy probably feels that she has lost her foremost physicist. He was anxious, up to the last, for information about every new discovery, and showed himself capable of appreciating results in many departments of physics. He was well known by reputation in this country as a thinker and worker of exceptional keenness and width of outlook. OLIVER LODGE.

A REUTER message from Stockholm announces the death, at seventy-seven years of age, of ADMIRAL A. L. PALANDER, who was in command of Baron Nordenskiöld's vessel, the *Vega*, which completed the navigation of the North-East passage from the Atlantic to the Pacific along the north coast of Asia (1878–79). Admiral Palander was an honorary corresponding member of the Royal Geographical Society and of many other scientific societies both in Sweden and abroad.

Notes.

A MOVEMENT set on foot in the early part of last year for the founding of an institution or society the membership of which should be open to those particularly interested in problems connected with the fields of administration and organisation in relation to industrial enterprises was brought to a head at a public meeting held on April 26 last at the Central Hall, Westminster, by the appointment of a provisional organising committee which was instructed to prepare a draft constitution for such an institution, to be named the Institute of Industrial Administration. This committee presented its report, accompanied by a draft constitution embodying (1) a schedule of objects, (2) the conditions of membership, and (3) the form of government, at a public meeting held at the above-named hall on July 15. This draft constitution was, with slight amendments, adopted on the date last mentioned, and the first board of management, consisting of eighteen members representing a variety of industries, was elected on the same occasion. The objects of the institute as set out in the draft constitution are briefly as follows:—To promote the general advancement of knowledge relative to the principles of industrial administration and their applications; to facilitate the exchange of information and ideas regarding the principles and practice of industrial administration; to collect and publish information and proposals bearing on any aspect of industrial administration; and to co-operate with professional, industrial, or educational societies, organisations, or authorities in pursuance of these objects. The government of the institute is to be vested in an advisory council composed of honorary members and a board of management representing the various classes of membership of the institute. Mr. E. T. Elbourne was elected hon. secretary of the institute, the offices of which are temporarily located at 110 Victoria Street, Westminster, S.W.1.

THE U.S. National Research Council, with headquarters at Washington, has elected the following chairmen of its various divisions for the year beginning July 1, 1920:—Division of Foreign Relations: George E. Hale, director, Mount Wilson Observatory, Carnegie Institution of Washington. Government Division: Charles D. Walcott, secretary of the Smithsonian Institution and president of the National Academy of Sciences. Division of States Relations: John C. Merriam, professor of palæontology, University of California, and president-elect of the Carnegie Institution of Washington. Division of Educational Relations: Vernon Kellogg, professor of entomology, Stanford University, and permanent secretary of the National Research Council. Division of Industrial Relations: Harrison E. Howe. Research Information Service: Robert M. Yerkes. Division of Physical Sciences: Augustus Trowbridge, professor of physics, Princeton University. Division of Engineering: Comfort A. Adams, Lawrence professor of engineering, Harvard University. Division of Chemistry and Chemical Technology: Frederick G. Cottrell, director of the Bureau of Mines. Division of Geology and Geography: E. B. Mathews, professor of mineralogy and petrography, Johns Hopkins University. Division of Medical Sciences: George W. McCoy, director of the U.S. Hygienic Laboratory since 1915. Division of Biology and Agriculture: C. E. McClung, professor of zoology, University of Pennsylvania. Division of Anthropology and Psychology: Clark Wissler, curator of anthropology, American Museum of Natural History, New York.

THE Department of Scientific and Industrial Research has established four Sub-Committees to assist the Radio Research Board in the investigation of certain problems in connection with the work of the Board. The constitution of the Board and its Sub-Committees is at present as follows:—*Radio Research Board*: Admiral of the Fleet Sir Henry B.

Jackson (chairman), Comdr. J. S. C. Salmond (representing the Admiralty), Lt.-Col. A. G. T. Cusins (representing the War Office), Wing Comdr. A. D. Warrington Morris (representing the Air Ministry), Mr. E. H. Shaughnessy (representing the General Post Office), Sir J. E. Petavel (presenting the National Physical Laboratory), Sir Ernest Rutherford, and Prof. J. S. E. Townsend. *Sub-Committee A on the Propagation of Wireless Waves:* Dr. E. H. Rayner (chairman), Prof. E. H. Barton, Major J. R. Erskine-Murray, Prof. H. M. MacDonald, and Prof. J. W. Nicholson. *Sub-Committee B on Atmospherics:* Col. H. G. Lyons (chairman), Mr. A. A. Campbell Swinton, Prof. S. Chapman, Major H. P. T. Lefroy, Mr. G. L. Taylor, Mr. R. A. Watson Watt, and Mr. C. T. R. Wilson. *Sub-Committee C on Directional Wireless:* Mr. F. E. Smith (chairman), Mr. M. P. Hinton, Capt. C. T. Hughes, and Capt. J. Robinson. *Sub-Committee D on Thermionic Valves:* Prof. O. W. Richardson (chairman), Mr. E. V. Appleton, Capt. S. Brydon, Capt. H. L. Crowther, Prof. C. L. Fortescue, Mr. B. Hodgson, Prof. F. Horton, Major A. G. Lee, Mr. H. Morris Airey, Mr. R. L. Smith-Rose, and Prof. R. Whiddington.

THE following appointments have been made in connection with the Royal College of Physicians of London:—Dr. F. Parkes Weber, Mitchell lecturer, 1921; Dr. G. Graham, Goulstonian lecturer, 1921; Dr. T. Lewis, Oliver Sharpey lecturer, 1921; Dr. A. Whitfield, Lumleian lecturer, 1921; Dr. R. O. Moon, FitzPatrick lecturer, 1921; and Dr. G. M. Holmes, Croonian lecturer, 1922.

IT was resolved in the House of Commons on August 9 to provide a sum not exceeding 100,000*l.* as a guarantee against loss resulting from the holding of a British Empire Exhibition in London next year. The grant is conditional on the provision of a further sum of 500,000*l.* by the promoters of the enterprise.

WE learn from the *British Medical Journal* that the second International Congress of Comparative Pathology will be held at Rome in the spring of 1921 under the presidency of Prof. Perroncito. Communications should be sent to the secretary, Prof. Mario Tevi Della Vida, Via Palermo 58, Roma.

WITH the view of popularising scientific knowledge in Spain, a weekly periodical bearing the title of *Ibérica* has recently made its appearance. The journal contains current notes on scientific matters in Spain and Latin-America, general notes, and abstracts of important foreign scientific papers written in a manner that will appeal to the popular reader of average education. Each number also includes a monograph or an instalment of a monograph on some popular scientific subject written by a leading authority. The contents conclude with a bibliography of current scientific literature, and meteorological information. The weekly is published by the Observatorio del Ebro, Tortosa.

WE are glad to see that the British Museum authorities have begun to issue additions, naturally under present conditions of publication in a less attractive form, to the valuable series of Handbooks, such as those provided before the war for the Assyrian, Babylonian, Egyptian, and Ethnographic Galleries. The latest is an account by Sir E. A. Wallis Budge of the Egyptian "Book of the Dead." This is a vague title now commonly given to the first collection of funerary texts which the ancient Egyptian scribes composed for the benefit of the dead, consisting of spells and incantations, hymns and litanies, magical formulæ and names, words of power and prayers, which are found cut or painted on the walls of pyramids and tombs, and engraved on coffins, sarcophagi, and rolls of papyrus. The pamphlet, which is well supplied with illustrations, provides for the use of students and visitors to the galleries an admirable introduction to the study of the death rites and theories of the soul current among the ancient Egyptians.

UNDER the title of "The Medical History of Ishi," by Mr. Saxton T. Pope, the University of California has published in its American Archæological and Ethnological Series a remarkable study of human pathology. The subject of the monograph, Ishi, was the last Yahi Indian, who was brought to the University Hospital after his capture in 1911, and died from tuberculosis in 1916. "We see him first as the gaunt, hunted wild man, his hair burnt short, his body lean and sinewy, but his legs strong and capable of great endurance. He suggests the coyote in this character." At first civilisation agreed with him, but then came a gradual change. "His energy waned. He no longer was keen to shoot at targets with a bow. His skin became darker." Then he contracted another cold and his malady increased. This monograph is supplied with full statistics of his case and excellent photographs and illustrations—most valuable for the study of the life-history of a Californian Indian, the last of his race.

A REMARKABLE stone bowl now deposited in the Museo Arqueológico, Madrid, is described in the July issue of *Man* by Mr. B. Glanvill Corney. It was obtained in 1775 at Tahiti by Máximo Rodríguez, a creole of Lima, and it was brought to that city in a Spanish ship-of-war, being finally sent to Spain in 1788. It is made of the hard, compact, black stone of which adze-blades and pestles for crushing taro and bread-fruit of the Society Islands were formed, and which was quarried only in the remote island called Maurua. It is not quite certain for what purpose this bowl was used. The local chiefs believe it to have been a sacred potion bowl, in which herbal draughts were prepared by trituration and infusion by the medico-sacerdotal functionaries. Others suppose that the function of the bowl was to receive viscera of victims sacrificed, and possibly it was used for some form of augury by inspection of the entrails of sacrificial victims. The bowl thus suggests interesting problems which, it may be hoped, further research will enable us to solve.

THE *Medical Record* for March 27 contains an interesting paper by Dr. C. B. Davenport on the influence of the male on the production of twins. It is well known that twins may be biovulate or

uniovulate, the latter type having a single chorion, and it is found that about 1 per cent. of all human births are plural births. But in the relatives of mothers who have repeated twins this proportion rises to 4·5 per cent., indicating the inheritance of twinning in the strain. Twinning is, however, almost equally frequent (4·2 per cent.) in the near relatives of the fathers of twins. The tendency to repetition of identical twins is even higher than when both types are considered together. Double ovulation is far commoner (frequency 5–10 per cent.) than twin births, and here the male factor comes in, for it has now to be recognised that human germ-cells frequently contain lethal factors which arrest development at an early stage, or may even prevent more than one egg being fertilised. In relation to this is the fact that highly fecund families more frequently have twins. Human beings thus possess the biovulate type of twinning found in carnivora, herbivora, and rodentia, and also the uniovulate type found in the armadillo, which regularly produces four young of the same sex at a birth by budding from the young embryo.

THAT the Philippine hawksbill turtle (*Eremochelys imbricata*) is in dire need of stringent protection is evident from the account of this species given in the *Philippine Journal of Science* (vol. xvi., No. 2) by Mr. E. H. Taylor, of the Bureau of Science, Manila. Practically all the Philippine tortoiseshell is brought into the market by the native fishermen, who are so eager to secure their prizes that they wait for days for the arrival of the female to lay her eggs on the beach. Often she is speared before a single egg is laid. Should they have patience enough to allow her to fill the "nest" the end is the same, for every egg is eaten. Obviously it will not be long before this source of revenue is lost for ever.

THE August number of *Conquest*, a magazine devoted to the popularisation of science, is a model of what such magazines should be, for not only are its contents designed to appeal to a wide circle of readers, but also every article is lucidly written and well illustrated. Taking subjects at random—for it would be difficult to make a deliberate choice—one may mention the essay by Mr. R. I. Pocock on the common animals of the sea-shore, that on wild white clover by Mr. J. J. Ward, and the article on the Davon micro-telescope by Mr. F. Talbot. Besides these are not less fascinating talks on the ships of the future by Mr. W. Horsnaill, on seaside meteorology by Mr. Joseph Elgie, and on the sands of the sea-shore by Mr. C. Carus Wilson.

THE attention of those who are interested in the campaign against rats may be directed to the second edition of Mr. M. A. C. Hinton's pamphlet (67 pp., 2 plates and 6 text-figures) which has been recently issued by the British Museum (Natural History). This work contains an excellent summary of the characters, habits, and economic importance of rats, and of the relation of rats to the spread of disease in man and animals. In this edition additional details are given on the rate of increase of rats, and reference is made to the occurrence in the rat of *Spirochaeta icterohaemorrhagiae*, the organism of spirochætal jaundice (Weil's disease) in man. After emphasising the urgent need for action against the large rat population of Great Britain, Mr. Hinton gives a concise account of the chief repressive measures. Barium carbonate is recommended as the safest poison, mixed in the proportion of one part with eight parts of oatmeal, and made up with a little water into a stiff dough. Among other methods to which attention is directed are trapping, which should be continuous and systematic, and placing in the run-ways of the rats birdlime trays with an attractive bait in the centre—a method which has given good results in Liverpool, London, and elsewhere.

ITALIAN biologists are to be congratulated on their enterprise in founding, in difficult circumstances, a new biological publication, *Revista di Biologia*, which is published bimonthly in Rome, and is edited by Profs. Gustavo Brunelli and Osvaldo Polimanti. The review is to be devoted largely to the consideration of problems of general biological interest, but its pages are also open to record the results of researches in special subjects. Six fascicles, forming the first volume of 744 pages, have recently reached us. Prof. Brunelli contributes to the first fascicle a vigorous article on the place which science, and especially biology, should occupy in the national life of Italy. He points out that the future of Italy is essentially bound up with agriculture and problems of the land, and that in the economic development of the nation biology must therefore take a leading art. He pleads also for more attention to hydrobiology, and for a closer co-operation between medical practitioners and biologists—for instance, in anti-malarial measures and in social hygiene generally. Among the special articles two may be briefly referred to: the first by Prof. Pierantoni on physiological symbiosis, with special reference to the part played by symbiotic organisms in light-production in luminous organs, and the second by Prof. Enriques on the results of experiments in breeding blow-flies (*Calliphora erythrocephala*), in which he shows that while some of the pairings give rise to a high proportion of living offspring, other pairings produce larvæ about one-fourth of which, although kept under optimum conditions, cease to feed after two or three days and die. Prof. Enriques does not consider that the explanation of Morgan, in his important work on lethal factors in Drosophila, holds for Calliphora. The *Revista* will not only fulfil its object in stimulating and encouraging biological research in Italy, but will also afford workers in other countries a ready means of keeping in touch with the chief lines of research of Italian biologists, and we cordially wish it success.

DR. R. RUGGLES GATES has given (Proc. Roy. Soc. London, B, vol. xci., 1920, pp. 216–23) a preliminary account of the meiotic phenomena in the pollen mother-cells and tapetum of lettuce, in which several matters of general bearing on cytological conceptions and on problems of genetics are considered. The chromatin of the nuclei of the tapetal cells, particularly of the binucleate cells, exhibits the synaptic knot

and other appearances which have hitherto been observed only in spore mother-cells of plants and in the primary spermatocytes and oocytes of animals. In lettuce, therefore, there is the unusual condition of all transitions between tapetal and germinal cells. Dr. Gates's material also affords, in the earlier stages of formation of the diakinetic chromosomes, a good example of chiasmatypy—the crossing-over of two members of a pair of chromosomes—which has not hitherto been definitely described in plants, though it is now well known in certain animals, *e.g.* in the fruit-fly, Drosophila, in which the phenomenon has been interpreted by Morgan and his collaborators as the probable basis of the crossing-over of factors. Another observation of much interest on the meiotic chromosomes of lettuce is the tendency for one or two pairs of the bivalent chromosomes to coalesce more or less completely on the equatorial plate of the heterotypic spindle. There is no evidence that such coalesced chromosome pairs pass over bodily to one pole of the spindle; rather they will both split in the usual way, but the manner of their previous coalescence will determine the nature of their distribution—whether, for instance, the paternal halves of each chromosome will go to the same pole or to opposite poles of the spindle. There is here a possible basis for the phenomena of partial coupling and repulsion, apart altogether from the crossing-over phenomena, which latter are based on relations between the two members of a pair of chromosomes in their earlier post-synaptic stages.

IN vol. xvii., No. 4 (October–December, 1919), of the Bulletin of the Imperial Institute Mr. W. Bevan, Director of Agriculture in Cyprus, continues his account of the agricultural industries of the island. Among the more interesting products discussed by Mr. Bevan are fodders and feeding-stuffs (including the carob bean), essential oils and perfumes, oils and oilseeds, fibres (including cotton and silk), drugs, and tobacco. Certain minor agricultural industries are also described. The reports of recent investigations at the institute have reference to fibres from India, Africa, and the West Indies, the utilisation of New Zealand hemp-waste, Pappea seeds from South Africa as a source of oil, Cyprus castor-seed, and distillation trials with talh wood (*Acacia Seyal*) from the Sudan. The general articles include an account of the present position of Para rubber-seed as a source of oil and feeding-cake, in which it is pointed out that the possibility of exploitation very largely depends upon the cost of collecting the seed on the plantations. A further article deals with cassava as a source of industrial starch and alcohol. As usual, much useful information is recorded as notes and in the section devoted to recent progress in agriculture and the development of natural resources. We observe that H.R.H. the Prince of Wales has arranged for a selection of the presents and addresses received during his visit to Canada to be exhibited at the Imperial Institute. An index to vol. xvii. of the Bulletin is included in this part.

IN many respects we pay too little attention to our West Indian Possessions. The present difficulties of communication hinder visits from our own men of science, and it is natural that those of the neighbouring United States should undertake tasks that we regretfully leave undone. Thus we learn from the Report of the American Museum of Natural History that towards the end of last year Mr. H. E. Anthony, who had previously secured many interesting mammalian remains from the caves of Cuba and Porto Rico, extended his researches to Jamaica, whence the skull of a marine mammal was the only example known. His hunt was successful, but the collections remain to be worked out. They are certain to throw light on the nature of former connection with the mainland. That we are not altogether idle may, however, be gathered from the fact that a collection of fossil sea-urchins from Antigua and Anguilla, made by Prof. J. W. Gregory some years ago, was reported on by Dr. J. Lambert, of Troyes, during the war, and is now being arranged in the geological department of the British Museum. That department has also been presented by Dr. C. T. Trechmann with an excellent dried specimen of the recent crinoid Holopus, rare because it grows under ledges of reef-rock and so escapes the dredge, instructive because of its adaptation in form to that peculiar position. This individual comes from Barbados, on which island Dr. Trechmann has recently spent some months investigating the raised reefs and collecting their fossils. None the less, the West Indies still present a large field for research, and British labourers are all too few.

THE *Agricultural News* of May 29 has an article on camphor-growing in the British Empire, based on a contribution by Prof. P. Carmody, formerly Director of Agriculture in Trinidad, to the *Times Trade Supplement*. The chief source of commercial camphor is Formosa, and the Japanese monopoly has led to an enormous increase in price in recent years. Various, but so far not commercially successful, attempts have been made in camphor cultivation within the Empire, namely, in Ceylon, the Federated Malay States, Mauritius, and the West Indies; in some cases distillation tests have shown a satisfactory yield, but in Mauritius and the West Indies the prunings may yield only oil and no solid camphor. Experimenting in Trinidad, Prof. Carmody found that trees grown in the Botanic Garden made very poor growth, but when transplanted to better soil the growth was satisfactory, and a normal yield of solid camphor was obtained. It is suggested that, owing to their bushy, evergreen habit, camphor-trees might be used as a windbreak in cacao cultivation. The successful cultivation of camphor within the Empire is no longer doubtful if a few necessary precautions are adopted. Seeds or seedlings from trees that yield no solid camphor must not be used; stiff clay soil must be avoided; in good average soil not more than 300 trees to the acre should be grown; and a sufficient area should be cultivated for economical distillation. When the trees are four or five years old they can be clipped, and thereafter three or four times a year. The same journal directs attention to the development of other sources of camphor, namely, rosemary in Spain, species of Artemisia, and the swamp-bay (*Persea pubescens*) in California.

METEOROLOGICAL observations made at secondary stations in Netherlands East India have recently been published for 1917. Since the publication of the previous volume a well-equipped meteorological station has been started at the aërodrome at Sockamiskin. Cloud observations have been almost wholly discontinued, and sunshine records are substituted; the cloud estimations (0–10) are said not to be trustworthy—which is scarcely surprising, since it is stated that the lower half of the sky was not taken into account, and that density had its say. Sunshine observations are from Jordan recorders, but the Campbell-Stokes recorder would give results more comparable with European observations. In addition to the ordinary detailed observations of rainfall, tables under the heading of "cloud-bursts" are given practically for all stations, which show the individual instances of rainfall of 1 mm. and more per minute, the minimum duration being five minutes. At Batavia the maximum mean monthly air-pressure occurred in August, and the minimum in April. July was the warmest month and December the coldest. The mean relative humidity, saturation being expressed as 1000, ranged from 879 in February to 793 in August. The percentage of bright sunshine was greatest in August and least in January. By far the greatest amount of rain falls in the winter months, January being the wettest, whilst May and June are the driest months. Wind results are given at only a few stations, but the observations clearly indicate a diurnal range in direction and velocity. A more complete discussion of winds would be of value for aeronautics, whilst the movement and, if practicable, the height and speed of clouds would add much to a better knowledge of the upper air.

THE *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* for March–April gives a full report of the work of M. Martial Entat on the destructive effect of light on certain materials such as textiles, dopes, and rubberised fabrics. It is difficult, if not impossible, in these climates to make quantitative measurements of the effect in the case of sunlight, and M. Entat accordingly used ultra-violet light from a mercury-vapour lamp in his experiments. He found that the mercury lamp was twenty times as effective as full sunlight in its destructive action on such materials. As is now well known, considerable protection may be afforded by the use of various dyes for absorbing the ultra-violet light. M. Entat's experiments indicate that the dyes commonly employed in aviation for protecting the fabric of aircraft have a "coefficient of protection" of from 50–75 per cent., the most efficient being the red dye from quinoline. A spectrographic measurement of the absorption of the ultra-violet light placed the various dyes in the same order as the tensile tests on the dye-protected fabrics which had been exposed to the rays. Experiments similar to those of M. Entat were carried out during the war at the Royal Aircraft Establishment at Farnborough. An account of the work was given by Dr. Aston to the Royal Aeronautical Society last year.

No. 4 of Abstracts of Papers in Scientific Transactions and Periodicals, published as a supplement to the minutes of the Proceedings of the Institution of Civil Engineers, contains a large number of brief abstracts taken from papers and periodicals published outside the United Kingdom. These are classified under the main headings of (1) measurement, measuring, and recording instruments; (2) engineering materials; (3) structures; (4) transformation, transmission, and distribution of energy; (5) mechanical processes, appliances, and apparatus; (6) specialised engineering practice; (7) economics, etc. There are several subdivisions to each of these main headings. It is not easy to produce abstracts which shall contain the information required and thus obviate the necessity for those interested having to consult the original papers; we note that these abstracts are satisfactory in this respect, and therefore provide a mine of information which we trust will be available to engineers who are outside the ranks of the Institution of Civil Engineers and would gladly purchase the Abstracts. The editing is somewhat loose occasionally; thus we note on p. 16 that an acceleration has been stated as "slightly more than 2 ft. per sec." A slip of this kind would have to pay a penalty at the Institution examinations.

THE special requirements in dental radiography are met by the radiator dental type of Coolidge tube, obtainable from the British Thomson-Houston Co., Ltd. This embodies the original features of the radiator type of tube whereby a large portion of the heat generated is conducted away by a copper radiator, but, in addition, the new tube allows greater proximity of the anode to the part under exposure. The cathode-arm extends 2 in. from the bulb at right angles to the anode-arm; this method of construction secures the emission of the X-rays in a line with the axis of the anode. The cathode circuit is earthed, so that there is only one high-tension wire, which is connected to the part of the tube most remote from the subject under exposure; this allows a minimum distance between the dental film and the focal spot, with consequent reduction in the time of exposure. The tube is self-rectifying within the limits of its allowable energy output, and is designed for an input not exceeding 10 milliamperes at an alternative spark-gap of about 3 in. The tube being designed to run only under specified electrical conditions, the manipulations are reduced to a minimum, and the only variable left in the hands of the operator is the time for which the film is to be exposed. In dental radiography this attempt at standardisation and simplification of procedure is likely to meet with considerable success.

MR. A. THORBURN, whose sumptuous volumes, "British Birds" and "A Naturalist's Sketch Book," have been so well received, is bringing out through Messrs. Longmans and Co. a companion work entitled "British Mammals." It will be in two volumes and contain fifty plates in colour and many illustrations in black-and-white. Vol. i. is promised for the coming autumn, and vol. ii. for the spring of next year.

Our Astronomical Column.

AN INTERESTING METEORITE.—Vol. lvii. of the Proceedings of the United States National Museum contains an analysis by Mr. G. P. Merrill of a meteorite that was seen to fall at Cumberland Fells, Kentucky, on April 9, 1919. It is stated that if the object had not been seen to fall, its meteoric character would not have been suspected. It is a "meteoric breccia composed of fragments of two quite dissimilar stones." The lighter-coloured portion contained 55 per cent. silica, 39 per cent. magnesia, 3 per cent. ferrous oxide, with traces of some seventeen other compounds. The darker portion, which more closely resembles other analysed meteors, contains 42 per cent. silica, 9 per cent ferrous oxide, 28 per cent. magnesia, 12 per cent. iron, etc. "Apparently the admixture of the two kinds of fragments took place prior to the evident compression."

The author conjectures that it is evidence of the destruction of some pre-existing planet, but the suggestion seems more reasonable that it is an earth-born meteor expelled in a mighty eruption in long-past ages. Sir Robert Ball was a strong advocate of the terrestrial origin of meteors, and it appears tenable in cases where the relative velocity is not very high. A lunar origin was suggested by Prof. Sampson; this also is preferable to the postulate of some purely hypothetical planet.

THE UNION OBSERVATORY, JOHANNESBURG.—Circular No. 47 of this observatory contains a search for proper motions by the blink method on two plates taken at Paris in 1887 and 1914. The region is R.A. 18h. 35m., N. decl. 31° 10′. The plates have already been measured at Paris, and the region is included in the Greenwich 1910 Catalogue, so the research was intended as a test of the comparative efficiency of the blink method. The result shows that it is undoubtedly the most rapid way of detecting all the displacements, but, of course, the method is purely differential, and absolute motions can be found only by using meridian observations of the reference stars on the plate. In the present case comparison with the Greenwich catalogue shows that the stellar background is moving 3.8″ per century towards 113°, so that the blink results are referred to an origin moving in this manner. It is found that each of the three methods of examining the region has revealed some motions not shown by the others, so that they all have their use. Mr. Innes gives the following summary of his results:—Two stars moving more than 20″ per century, eight between 20″ and 10″, seven between 10″ and 8″, twenty-seven between 8″ and 6″, and forty-nine (probably incomplete) below 6″.

GALACTIC CONDENSATION.—The results of an examination of stellar density at different galactic latitudes, derived from plates taken at Sydney, are given in Circular No. 47 of the Union Observatory, Johannesburg. The plates are fairly complete down to magnitude 15; there are very few of these faintest stars in the regions remote from the galaxy; the galactic condensation of the fainter stars is greater than that deduced at Groningen. Incidentally, Mr. Innes criticises Prof. Eddington's statement in "Stellar Movements" that the depth of the stellar system is about three times as great towards the galaxy as towards its poles, and also that the stellar density in the galactic regions is greater than in the polar ones. Mr. Innes shows that, granting, as he does, the latter statement, the ratio of depths becomes very much less than three to one; in other words, the stellar system is more spherical than previously stated.

The British Empire Forestry Conference

THE Forestry Commission, constituted in November, 1919, has not been long in bringing about what promises to be one of the most important events in the history of forestry in the British Empire. We allude to the British Empire Forestry Conference which, with intervals for visits to certain selected forest areas in England and Scotland, held its sittings in London on July 7-22 under the chairmanship of Lord Lovat. The delegates included representatives from the United Kingdom, Australia, Canada, India, Newfoundland, New Zealand, South Africa, the Sudan, and most of the Crown Colonies. The main objects of the conference were to bring together such information as exists at present regarding the forest resources of the Empire, and to devise means of forming a more accurate estimate of these resources and of developing them to the utmost; to focus attention on the necessity for a more rational forest policy in the various parts of the Empire; to bring to light some of the more salient problems connected with technical forestry; and to consider certain important questions relating to forestry education and research.

No more opportune time could have been selected for such a conference. Of the many forcible lessons taught us by the Great War there are few which require to be taken more to heart than the lesson taught us in regard to the maintenance of our timber supplies. The view once held, that the timber resources of the Empire are inexhaustible, is no longer tenable, for we are already faced with a probable world-shortage of timber which will become more and more acute if steps are not taken to prevent reckless waste and to ensure that production keeps pace with exploitation. In the affairs of our Empire the scientific aspect of forestry has been too long relegated to the background, largely owing to misapprehension as to its true aims For forestry, no less than agriculture, is an industry based on the productive capacity of the land, with this important difference: that whereas agricultural crops are harvested within a year, forest crops may take a century or more to mature. Hence in forestry, far more than in agriculture, the State must take a direct interest in the growing of the crops concerned, for the success of which continuity of management based on scientific principles is the keynote.

Among the most important proposals approved of by the conference was that relating to the formation of an Imperial Forestry Bureau to be located in London. This Bureau, constituted somewhat on the lines of the Imperial Mineral Resources Bureau, would act as a clearing-house of information on all subjects connected with forestry and forest products. It would undertake to collect, co-ordinate, and disseminate information on forest education, research, policy and administration, and the resources, utilisation, consumption, and requirements of timber and other forest products. In this way the Bureau cannot fail to prove a valuable link in forest matters between the various parts of the Empire.

Among the more important specific questions which it is hoped the Bureau will lose no time in taking up are the standardisation of technical terms used in forestry and the correct identification of timbers in commercial use, with the standardisation of their trade names so far as this is possible.

The question of forest research work was fully considered. The conference held that this work, for various reasons, is primarily the concern of the State. Speaking generally, forest research is divisible into two main branches: (1) that dealing with the grow-

ing of forest crops, and (2) that dealing with the utilisation of timber and other forest products. Each of these two main branches can be considered from two points of view, namely, the general and the local, the former being concerned with the principles and methods governing research work, and the latter with the application of principles to a limited range of conditions. General research may, consequently, be conducted at one centre for very wide areas, while local research must be conducted on the spot. Although the two main branches of research are intimately connected, from their nature they cannot always be conducted at the same institution; it is, however, impossible to lay down any hard-and-fast rule in the matter, and, provided adequate co-ordination is secured, there is no reason why the two branches of research may not be conducted successfully either together or apart, as circumstances may dictate. Most of the research problems of outstanding importance fall under the head of sylvicultural, statistical (that is, the collection and collation of data dealing with rate of growth and production), or technological. The conference recorded the opinion that in no part of the Empire is sufficient attention paid to the investigation of sylvicultural and statistical problems, considering their great importance in connection with the future maintenance and economic working of the forests; accordingly it recommended that each part of the Empire should include in its forest service at least one research officer, and that adequate funds should be placed at his disposal to ensure progress in these branches of research.

Specific proposals were made in respect of forest research work in different parts of the Empire, and it may be of interest to note the views of the conference in regard to the organisation of work in the United Kingdom. It was held that requirements would be met by the establishment of (1) a research institute to deal with problems connected with the growing of forest crops, and (2) a research organisation which should include a central institute to deal with problems connected with the utilisation of forest products. It was proposed that the latter should be governed by a research board composed of official and non-official members, the board being an executive body similar to the research boards established by the Department of Scientific and Industrial Research. Such a board, which would have definite sums allotted to it for research on forest products, would decide where any particular problem should be investigated, and distribute the funds at its disposal accordingly.

The question of forestry education in its various aspects was fully discussed, and although this question presented numerous difficulties the conference succeeded in clearing the ground to a considerable extent. In approaching this question sufficient discrimination is not always shown between the training of forest officers for service in different parts of the Empire and the training in forestry of owners and managers of private woodlands and others who do not desire to take the course of instruction required for the various forest services. In the United Kingdom the training of owners and managers of private woodlands is a matter of great importance in view of the large proportion of such woodlands existing in the British Isles. Such training, however, must be carried out on somewhat different lines from the training of forest officers for the various parts of the Empire. So far as concerns the latter, the conference held that one institution should be established in Britain for the training of forest officers for the United Kingdom and for those parts of the Empire which, for climatic or other reasons, may be unable to establish such an institution of their own, or desire to send students to Britain for training. Students would be selected from graduates who have taken honours in science at any recognised university. An integral part of the work of the institution would be to arrange supplementary courses at suitable centres for students requiring special qualifications, and also special courses for forest officers from any part of the Empire, whether at the institution itself or at centres of training in other parts of the world. A department of research into the formation, tending, and protection of forests would be associated with the training institution.

In view of the success of the conference just held, and of the far-reaching results likely to follow, it is proposed that this should be only the first of a series of similar forestry conferences to be held at intervals of a few years in different parts of the Empire. Such conferences cannot fail to stimulate public opinion in regard to what is a very important national question or to advance the cause of scientific and economic forestry, which has hitherto been too much neglected by the Empire at large.

Colloidal Electrolytes.

COLLOIDAL electrolytes are defined as solutions of salts in which one ion has been replaced by a heavily hydrated multivalent "micelle," or cluster of ions, carrying an electrical charge equal to the sum of the charges of the constituent ions, and (by reason of its reduced resistance to movement through the fluid) serving as an excellent conductor of electricity. This new class of electrolytes probably includes most organic compounds, containing more than eight carbon atoms, which are capable of forming ions—*e.g.* proteins, dyes, indicators, sulphonates, and soaps; it may also include inorganic compounds, such as chromium salts, tungstates, silicates, etc., which have a marked tendency to form highly complex ions. Work on this subject has been in progress in the laboratory of physical chemistry at the University of Bristol during a period of several years, and the results of the investigation have recently been published by Prof. J. W. McBain in papers communicated to the Royal Society (Proc. R.S., 1920, A, 97, 44–65), to the Chemical Society (Trans C.S., 1919, 115, 1279–1300), and to the American Chemical Society.

The earlier experiments at Bristol showed that soap solutions possess a high degree of electrical conductivity, not only in dilute, but also in concentrated, solutions. This electrical conductivity could not be attributed to hydrolysis, since the absence of all but mere traces of free alkali could be demonstrated by measurements both of rate of catalysis and of electro-motive force. The high conductivity of the solution must therefore be due to the soap itself. Experiments on the depression of the freezing-point of soap solutions, and later experiments on the lowering of vapour-pressure, showed that, whilst the salts of the simpler fatty acids have an osmotic activity diminishing steadily as the concentration increases, salts of the higher homologues (from C_{12} upwards) have an osmotic activity which passes through a minimum and then through a maximum before finally diminishing to a low value in the most concentrated solutions. The high osmotic activity of the soaps in concentrated solutions, coupled with the remarkable electrical conductivity of these solutions, is explained most satisfactorily by the theory of the ionic micelle. In its simplest form this micelle might be merely a polymer of the negative radical, in a strongly hydrated condition, but it is possible, and even

probable, that the micelle carries, condensed on its surface, not only a considerable proportion of the solvent, but also much of the undissociated solute.

In reference to the general aspects of this work, two comments may be made. In the first place, Prof. McBain, in attempting to determine the real character of soap solutions, has tackled one of the big outstanding problems that called most urgently for a clear solution; the six years which he has devoted to this work have therefore been used far more advantageously than in solving the hosts of minor problems which appeal so strongly to workers who are anxious for immediate publication of results. In the second place, the elucidation of the nature of soap solutions by the theory of the ionic micelle is perhaps the biggest advance that has been made in the theory of electrolytic dissociation since the early work of Arrhenius and van't Hoff. Other workers, especially in physiology, have made use of similar ideas, but in no previous case has the experimental evidence been so complete or the theory established on so firm a basis as in the case of the soap solutions investigated in the Bristol laboratory. T. M. L.

Plant Culture in Denmark.

In Denmark during the past twenty years there have been great advances in the development of the various branches of plant culture. The organisation and aims of this work are described by Prof. F. Kolpin Ravn in a recent number of the *Scottish Journal of Agriculture* (vol. iii., No. 2, April, 1920). The first Danish experiments on plant culture were commenced in 1860 by B. S. Jorgensen, who took Rothamsted as his model. Later development followed various lines, but one of the most famous pioneers was P. Nielson, who in 1886 became director of the first State experiment station, and laid the foundation of the extensive State experimental work carried on at the present day. In 1893 the root experiments which had previously been instituted by the Society for the Improvement of Cultivated Plants were placed under the control of the State experiment stations, and in 1903 the same thing happened with the wheat and malt-barley experiments of the Royal Agricultural Society.

During the closing years of the nineteenth century various agricultural societies became keenly interested in plant-culture experiments, and by means of special committees on plant industry a large amount of useful work has been carried out. Since 1905 an increasing number of field experiments have been started by the "smallholders'" societies, the members of which have taken up this experimental work with great enthusiasm. All this work is carried out either by the State itself or by institutions with the aid of Government subsidies, the State contributing annually about 25,000*l.* for the development of plant culture. There are eleven State experiment stations, eight of which specialise in agricultural problems and the other three in horticultural problems. Field experiments and laboratory work are included, while various subdepartments carry out investigations on weeds, on plant diseases, and on chemical, physical, and bacteriological problems. The State stations deal with those problems requiring lengthy and very accurate experiments, while the agricultural societies conduct experiments designed to throw light on matters of actual and of local interest. The majority of these experiments deal with the use of fertilisers, and hints as to the final results appear in a very short time. Another section of experimental work is that of plant breeding, which is practised both by public and by private institutions. This work is supported by the State experiment stations in that all novelties appearing on the market are accurately tested by variety and strain experiments without regard to the person or institution by whom they have been grown. In this way a competition open to all seed-growers and plant-breeders is formed, and this excites great interest, since the results of the experiments determine the market price of the seed.

Prof. Ravn points out that although the work appears to be very much scattered, yet the various institutions keep in close touch with each other by joint meetings, etc., when the general lines of work are discussed and common methods decided upon. It is thought that this type of organisation is most favourable to the development of initiative and to the proper testing of new ideas and products.

Short-period Meteorological Variations.

No. 102 of the Publications of the Royal Netherlands Meteorological Institute contains Dr. E. van Rijckevorsel's eleventh communication on the subject of secondary maxima and minima. The author maintains that if sufficient years be taken to mask the long-period variations, and mean values for an element such as temperature or barometric pressure be set down for each day in the year, the resulting figures for any station will show a series of waves of an average period of between ten and eleven days, so that thirty-five maxima appear in the annual curve.

The present contribution is devoted principally to a comparison of the barometer values for thirty-three stations from periods varying from forty-three years at Haparanda to only four years at Honolulu and St. Vincent, with those obtained in the long series of seventy-two years (1838 to 1909) at Christiania. The Christiania data are analysed more thoroughly, as the whole series is divided into two thirty-six-year periods A and B; and also the first twenty-four years of A, the last twelve years of B, and the first six years of B are treated separately. Moreover, the data from Christiania, Nertchinsk, and Innsbruck have been specially examined, the means from an equal number of years of maximum and minimum sun-spots having been taken for each of the three stations. Innsbruck is not one of the thirty-three stations, which are themselves grouped according to latitude, the mean latitude of the groups being 67°, 52°, 42°, and 21° respectively. They are fairly well distributed in longitude. Diagrams are given of twelve pulsations, the groups being separated and the stations in each group arranged in order of longitude, and an attempt is made to indicate a sort of systematic variation in the agreement between the several curves.

A final diagram gives apparently ideal curves of temperature and pressure through the year, showing the subsidiary period only affected by some annual variation which flattens the waves at the equinoxes, compared with actual values from fifteen years' data at Bucharest. Dr. van Rijckevorsel has devoted himself for many years to this particular investigation, but it does not seem to have enlisted much support up to the present time. W. W. B.

University and Educational Intelligence.

Cambridge.—Prof. S. J. Hickson, of Manchester, has been elected an honorary fellow of Downing College. Mr. A. J. Berry has been re-elected to a fellowship.

Glasgow.—Dr. A. J. Ballantyne has been appointed lecturer in ophthalmology in succession to Dr. M. Ramsay.

LIVERPOOL.—A contribution of 10,000*l.* in support of the University Appeal Fund has been made by the Cunard Steamship Co., Ltd.

The Pacific Steam Navigation Co., Liverpool, has made a contribution of 1000*l.* to the same fund.

THE directors of Messrs. Brunner, Mond, and Co. were authorised at an extraordinary meeting held at Liverpool on August 4 to distribute 100,000*l.* out of the investment surplus reserve account to universities or other scientific institutions in the United Kingdom for the furtherance of scientific education and research. Proposals for the allocation of this grant are under consideration, but no scheme has yet been adopted by the directors.

AN examination for the Aitchison memorial scholarship, of the value of 30*l.*, and tenable in the full-time day courses in technical optics at the Northampton Institute, Clerkenwell, will be held in September next. The scholarship is open to candidates of both sexes between sixteen and nineteen years of age. The compulsory subjects are English and elementary mathematics. The optional subjects, of which only two must be taken, are additional elementary mathematics, physics (heat, light, and sound), chemistry, electricity, and magnetism. Full particulars are given in a leaflet which can be obtained from the hon. secretary and treasurer, Mr. Henry F. Purser, 35 Charles Street, Hatton Garden, London, E.C.1.

NEWS has just reached us that Prof. A. T. De Lury was appointed some months ago to be head of the department of mathematics in the University of Toronto by the Board of Governors on the recommendation of the president of the University, Sir R. A. Falconer. The Staff, Council, and Senate have nothing to do with appointments, and the only check upon the action of the president and the Board of Governors is public opinion. Prof. De Lury has been a member of the teaching staff of the University for many years, and is the author of a number of mathematical text-books which have done service in the schools of the province of Ontario. He possesses high teaching ability, but has not been associated with the research activities which it should be the essential function of a university to create and foster. Without men engaged in the production of new knowledge the work of a university differs little from that of a secondary school preparing students for examinations. Toronto has won much distinction by the scientific investigations of such men as Profs. Macallum, McLennan, and Brodie, and it was hoped that the chair of mathematics would have been filled by someone who possesses the highest research qualifications in mathematics that Canada could produce. If Prof. De Lury can and will build up a strong research staff under him, he will be doing the best service to his University and extend the stimulating atmosphere which some of his scientific colleagues have given to the institution by their work.

AMONG the recent bulletins issued by the U.S. Bureau of Education, Washington, is one (No. 61) entitled "Public Discussion and Information Service of University Extension." It comprises some fifty pages octavo, and deals with the extra-mural activities of the numerous universities and library commissions of the various States. The bulletin submits that university extension should not only offer the opportunity of self-directed study for the great mass of persons who wish to continue systematically their preparation for personal advancement, but should also provide the indispensable connection between scientific knowledge and the everyday practice necessary for sound community development, between the facts accumulated through research and their application to the practical problems which must be met by individual communities in a democratic society. University education is not merely educational in the limited sense; it attempts to make facts, knowledge, and truth operative in the daily life of the people. The scope of university extension so interpreted includes bureaux of information, lecture schemes—club study and library service—assistance in debates and in other forms of public discussion, together with a novel institution known as the package-library service, by which is meant the compilation by specialists at each university or library centre of information of pamphlets, bulletins, clippings from articles in magazines and other sources on subjects and questions of interest to the public, which are sent on application to individuals or organisations in districts, however remote, within the State. Wisconsin, for example, had in 1918–19 more than 1000 subjects, and the Texas bureau 550, represented in their package-library collections, the contents of each of which are changed from time to time. They cover the whole domain of civic, economic, and State activities. The bulletin gives full particulars of the cost, methods, and organisation of the service, which might with much advantage be introduced into this country. The information bureaux were made much use of, since nearly 180,000 requests for information were received in fourteen States, and in twenty-four States the lectures arranged were attended by upwards of 2,000,000 persons.

Societies and Academies.

PARIS.

Academy of Sciences, July 19.—M. Henri Deslandres in the chair.—F. E. **Fournier**: The resistance of a fluid to the horizontal translation of a spindle-shaped or spherical body with deep immersion.—A. **Haller** and Mme. **Ramart-Lucas**: Bromohydrins and dibromo-derivatives obtained from the alkylallylacetophenones,

$$C_6H_5 \cdot CO \cdot CHR \cdot CH_2 \cdot CH{:}CH_2 \text{ and } C_6H_5 \cdot CO \cdot CRR_1 \cdot CH_2 \cdot CH{:}CH_2.$$

Compounds of the latter type give bromohydrins on treatment with bromine; under the same conditions methylallylacetophenone gives a stable dibromide, $C_6H_5 \cdot CO \cdot CH(CH_3) \cdot CH_2 \cdot CHBr \cdot CH_2Br$.—F. **Widal**, P. **Abrami**, and N. **Iancovesco**: Proof of digestive hæmoclasia in the study of hepatic insufficiency. It has been shown in an earlier communication that for some time after a nitrogenous meal incompletely disintegrated proteids pass into the portal vein from the intestine, and that these substances are prevented from passing into the general circulation by the normal action of the liver. This has now been applied clinically after a meal of 200 grams of milk or of meat and eggs. No symptoms of hæmoclasia are given by healthy subjects or by subjects suffering from various illnesses provided the liver is in a normal condition, but with the liver diseased a similar meal is followed by a hæmoclasic crisis, with alterations in the number of white corpuscles, arterial pressure, coagulability of the blood, and refractometric index of the serum. These symptoms have proved capable of detecting latent disease of the liver when the usual signs are wanting.—E. **Ariès**: The determination of the last of the three functions which defines the equation of state of ether.—G. **Fubini**: Automorphic functions.—G. J. **Remoundos**: The modulus and zeroes of analytical functions.—A. **Petot**: The spherical representation of surfaces and the correspondence by parallel tangent planes.—G. **Bruhat**: Remarks on the compression of saturated

vapours.—M. **Sauzin**: The propagation of sustained electrical oscillations in water and the dielectric constant of water. Oscillations with wave-lengths in air of 444 cm. and 242 cm. gave 73 as the dielectric constant of distilled water—a little lower than the usually accepted figure, 80.—C. **Zenghelis**: New researches on the action of gases in a very fine state of division. A continuation of experiments described in a previous paper on the same subject. From a mixture of hydrogen and carbon dioxide, formaldehyde and its condensation products were identified. The reduction is favoured by light, especially by the ultra-violet rays.—J. **Cournot**: The annealing of electrolytic iron. The removal of hydrogen from electrolytic iron by annealing can be effected by heating for two hours at 950° C. or one hour at 1050° C. At 850° C. or lower temperatures micrographic study and hardness determinations proved the annealing to be incomplete even after six hours' heating.—L. **Guillet**: Some new researches on special brasses. Studies of brasses containing cobalt, chromium, silver, and gold.—G. **Gire**: The oxidation of arsenious anhydride in alkaline medium in presence of ferrous sulphate.—G. **Denigès**: Iodic acid as a microchemical reagent characteristic of gaseous ammonia. A 10 per cent. solution of iodic acid gives characteristic crystals of ammonium iodate on exposure to gaseous ammonia. As little as 0·1 milligram of ammonia can be detected by this means.—A. **Desgrez** and J. **Meunier**: The incineration of organic matter with the view of determining its mineral constituents; application to blood analysis.—A. **Korczynski**, W. **Mrozinski**, and W. **Vielau**: New catalytic elements for the transformation of diazo-compounds. Salts of cobalt and nickel may replace copper salts in certain applications of Sandmeyer's reaction.—J. **Martinet** and O. **Dornier**: A new indigo colouring matter, 5-[dioxy-2:4-pyrimidine]-2-indolindigo.—H. **Hubert**: New contact phenomena of the diabases in Western French Africa.—A. **de Puymaly**: A new small green alga, *Prasiola leprosa*.—A. **Paillot**: The Œnocytoides and Teracytes.—A. **Dehorne**: Atypical characters in somatic mitosis in *Corethra plumicornis*.—B. **Guérithault**: The presence of copper in plants, and particularly in food of vegetable origin. Copper was present in forty-four materials of vegetable origin (vegetables, seeds, and fruits) in amounts varying between 9 and 63 milligrams per kilogram of dried substance.—A. **Krempf**: The last phases of the development of the endodermic metamerised organs of the larvæ of Anthozoa and the formation of the pharynx.—E. **Chatton**: Palisporogenesis: a mode of reproduction special to certain parasite Flagellæ.—J. **Feytaud**: Young colonies of the luminous Termite.—A. Ch. **Hollande** and P. **Vernier**: *Cocobacillus insectorum*, var. *malacosomae*, a pathogenic bacillus of the blood of the caterpillar, *Malacosoma castrensis*.

PHILADELPHIA.

American Philosophical Society, April 22.—Prof. W. B. Scott, president, in the chair.—Dr. L. M. **Haupt**: Beach-protection works.—Prof. D. W. **Johnson**: Geographic aspects of the Adriatic problem.—A. G. **Mayor**: The reefs of Tutuila, Samoa, in their relation to coral-reef theories.—Prof. H. F. **Reid**: Distribution of land and water on the earth. The conception of the land of the earth as being a deeply dissected and loosely joined together mass, with its centre about half-way between the equator and the poles, explains nearly all the characteristics of the distribution of land and water, such as the antipodal relation, the concentration of land about the North Pole and of water about the South Pole, etc.—Prof. E. C. **Kendall**: Thyroxin.—Dr. S. J. **Meltzer**: The dualistic conception of the processes of life. The dualistic conception of the life-processes may be presented as follows: Irritability is a characteristic property of all living tissues. Irritability means the property of the tissues to react with a change in each state to a proper stimulus. The change may consist in an excitation—an increase in activity, or an inhibition—a decrease in activity. Each and every state of life of the plain tissues or of the complex functions is a resultant from the combination of the two antagonistic factors, excitation and inhibition.—Dr. F. G. **Blake**: The relation of the *Bacillus influenzae* to influenza. The experiments described establish the etiological relationship of *Bacillus influenzae* to the type of bronchopneumonia with which the organism has been found constantly associated in man. They also prove that *B. influenzae* can initiate an infection of the upper respiratory tract and produce a disease that closely resembles influenza and is associated with the same complications as influenza. They do not prove that *B. influenzae* is the primary cause of influenza, however, since it is impossible to determine whether the disease produced in monkeys by inoculation with *B. influenzae* was actually identical with pandemic influenza.—Dr. W. E. **Dandy**: X-rays of the brain after injection of air into the ventricles of the brain and into the spinal canal.—Prof. J. D. **Prince**: Celt and Slav. Slavs and Celts are strikingly similar to each other in habits of mind and expression, although far removed geographically. The Russians, Poles, Czecho-Slovaks, Serbo-Croatians, and Bulgarians, all speaking Slavonic idioms, although racially very various, have certain marked traits in common which they all share with the Celts, viz. the Irish, Scottish, and Manx Gaels, the Armorican Bretons of France, the Welsh, still Celtic-speaking, and the Cornish, whose Celtic language is now extinct. The similarity between Slavs and Celts is twofold, viz. temperamental discontent and morbid joy in sorrow. As a concomitant of this discontent goes the spirit of quest after the unattainable, which is manifest in both Slavonic and Celtic trends of thought. The sun of common sense has never risen on either the Slav or the Celt, and it is doubtful whether the Slavs can exist very long without the guiding hand of strangers. The charm of the Celt and Slav is great and durable, but it is charm and not character, feeling and sentiment rather than thought and reasoning, which dominate the east and west of Europe alike.—Prof. R. B. **Dixon**: A new theory of Polynesian origins. The question of the racial origins of the Polynesian peoples has long attracted the attention of anthropologists. Previous studies have dealt mainly with small portions of the area, and have not satisfactorily correlated the various factors characterising physical types, or the Polynesian types with those of the rest of Oceania. The present study seeks to secure more satisfactory results by including the whole of Oceania and Eastern Asia in its scope. Following a method differing from those previously employed, a number of fundamental physical types are defined, and their distribution and that of their derivatives traced. One of these fundamental types unexpectedly proves to be Negrito, the other two most important ones being Negroid and Malayoid. The Negrito and Negroid types, being marginal in their distribution, are probably the older.—Prof. A. V. W. **Jackson**: The Zoroastrian doctrine of the freedom of the will. The purpose of this paper was to show the significance of the doctrine of the freedom of the will in the dualistic creed of Zoroaster more than 2500 years ago.—Prof. M. **Jastrow**, jun.: The Hittite civilisation. The Hittites seem to have been composed of a

conglomeration of various ethnic elements, and about 1500 B.C. a strong Hittite empire was located in northern Asia Minor which was powerful enough to threaten both Egypt on one side and Babylonia and Assyria on the other. These Hittites, moving along the historical highway across Asia Minor, left their rock monuments and their fortresses as traces of the power and civilisation which they developed. Their contact with Assyria appears to have been particularly close, and it is not impossible that the earliest rulers were actually Hittites. The "sons of Heth" associated in tradition with Abraham are Hittites, and there were Hittite generals in the army of the Jewish kings.—Prof. M. **Bloomfield**: The decipherment of the Hittite languages.—Prof. P. **Haupt**: The beginning of the Fourth Gospel. John i. 1 should be translated: "In the beginning was reason." Greek "logos" denotes both "word" and "reason." Logic is the science of reasoning. According to the Stoics, reason (Greek "logos") was the active principle in the formation of the universe.

The Control of Water Resources.

IN June, 1918, a Committee, with Sir John Snell as chairman, was appointed by the Board of Trade and the Ministry of Reconstruction "to examine and report upon the water-power resources of the United Kingdom and the extent to which they can be made available for industrial purposes." The Committee issued an Interim Report early in 1919, directing attention to nine large sources of water-power in Scotland which could be developed at once so as to supply electrical energy at economic rates. It was no doubt while investigating the conditions of water-power that the complexity of the general problem of the use of natural water was appreciated by the Committee, for in October, 1919, the terms of reference were extended by the Board of Trade to "consider what steps should be taken to ensure that the water resources of the country are properly conserved and fully and systematically utilised for all purposes." At the same time the Committee was strengthened by the addition of two officials of the Ministry of Health and three eminent water engineers. The enlarged Committee has issued a Report[1] dealing with the special subject of the new reference. It should be remembered that water for potable supplies must be delivered in a high state of purity, so that it cannot be collected from the surface in urban or agricultural areas. Water subject to organic impurities may, indeed, be rendered potable by chemical and bacteriological means, as Sir Alexander Houston has demonstrated on the citizens of Greater London. But many communities demand a natural and untreated supply, and this, in default of deep wells, can be obtained only from uncultivated moorlands, most of which in England and Wales have already been appropriated.

The present method of allocating supplies is for a local authority to select a suitable gathering ground and then to promote a private Bill in Parliament. The proposed scheme, after being found to conform to Standing Orders, is examined in turn by a Committee of each House, the members of which may or may not have some knowledge of water supply and of parliamentary usage. An able counsel urges the necessity and perfection of the scheme on the Committee and brings forward experts to prove that the selected area can yield enough water and no more than is required. Certain Government Departments have the right to report upon the Bill, *e.g.* the Ministry of Health with regard to the quality of the supply and the needs of the population, the Ministry of Agriculture and Fisheries with regard to land drainage and possible damage to fish, and the Board of Trade or Ministry of Transport with regard to any possible effect on navigation. If the promoters succeed in arriving at an arrangement with the public bodies and private persons who appear as opponents, their scheme is likely to be passed by the Committee without any very critical inquiry, and it may be that broad national aspects of the case are never considered at all.

In Scotland there is in most cases an alternative to the promotion of a private Bill, by obtaining a provisional Order from the Scottish Office after an inquiry by a joint Committee of both Houses of Parliament sitting in the locality, and not at Westminster. In the absence of opposition the Order is confirmed by Parliament without further examination. A multitude of public and private opponents have a *locus standi* with regard to a Water Bill, but the fundamental idea appears to be that opposition is a matter for individual interests, and that it is not the business of any impartial authority to ascertain the facts of any particular case in the public interest alone. Selfish opposition often makes the passage of a Water Supply Bill difficult, and in the case of water-power the difficulty is much greater, as alternative sources of power are merely a matter of price.

The Report before us gives the considered

[1] Board of Trade. Second Interim Report of the Water-Power Resources Committee. Presented to Parliament by Command of His Majesty. Pp. 28. Cmd. 776. (London: H.M. Stationery Office, 1920.) Price 4*d*.

opinion of the Committee on the question of the most desirable mechanism of control for the whole water resources of the country, and it is evident that some diversity of opinion had to be reconciled in arriving at it. One member, Mr. W. A. Tait, of Edinburgh, submits a Minority Report in which he considers that all the reforms required can be secured by improving the present system, both by assimilating the law of England to that of Scotland and by making certain simplifications in procedure. He holds that there is no justification for a new central water authority. One member signs the Majority Report with a reservation in which he deprecates the creation of a Water Commission, on the ground that the Ministry of Health, if strengthened, can deal adequately with the matter. Another signs with the reservation that he would have preferred a Central Department to deal with all water interests. The remaining seventeen members found the terms of the Majority Report sufficiently comprehensive and guarded to express their views.

One might imagine that the easiest way to simplify the confusion of contending water interests would be to create a Central Department for the United Kingdom to which all existing Departments should transfer their duties as regards water, and in which any additional powers which might be required should be vested. By the constitution of the Committee the water problem in Ireland was referred to a special Irish Sub-Committee, and recent events naturally confirm the policy of keeping Irish interests by themselves. But the Committee has not found it possible or expedient even to recommend the retention of Great Britain as a unit, and the scheme outlined refers in its entirety to England and Wales, Scottish interests being left to the Scottish Office.

It seems unfortunate, in the present state of public feeling, that a rearrangement of duties could not have been suggested which should avoid adding to the present number of officials; but, on the other hand, it is necessary to bear in mind that the Committee set itself to devise a practicable scheme which could be got to work with the minimum disturbance of existing Departments. Viewed as a workable compromise, the plan suggested by the Committee has sound qualities which probably compensate its obvious theoretical deficiencies.

The Committee points out that nine previous Royal Commissions and Select Committees which had considered water problems between 1866 and 1910 had concurred in recommending the creation of a central water authority to control the allocation of water, to act as an advisory body to Parliament, and to collect information as to water resources. Much fresh evidence was called by the Committee, and the final scheme for control put forward in this Report is as follows.

The allocation [illegible] in England and Wales [illegible] be entrusted to a [illegible] of four Commissi[illegible] appointed by the Minis[illegible] of Health, [illegible] whom their responsibility should be direct. [illegible] chairman of the Commission should be a Civil [illegible]vant or lawyer having ripe experience of administ[illegible] and legislation. The other three should be techn[illegible] members, all to be paid and to devote their whole [illegible] the work. An Interdepartmental Committee representing the "multiplicity of interests to be reconciled" and including representatives of various scientific services should be set up by statute to assist the Commissioners.

In order that the Commission may perform its duty of allocating water, its first concern is held to be to acquire all necessary information on the subject. This should be obtained from the Departments already engaged in collecting such data, particularly the Ordnance Survey, the Geological Survey, and the Meteorological Office; but as these do not cover the whole ground the Commission should be empowered to set up a Hydrometric Survey. The Commission should consult with the Scottish and Irish authorities with a view to the compilation of all records on a uniform system.

It is recommended that every proposal to take water from the surface or from underground, except for private domestic use, should be submitted to the Commission for its licence. If the Commission sees cause to withhold its consent, the promoters can still proceed by means of a private Bill; but if a licence is issued, they need apply only to the Department dealing with the particular use of water, and this Department should be empowered to grant an Order which, if unopposed, should take effect without confirmation by Parliament. Existing Departments are empowered to deal with all uses of water except water-power, and it is proposed to create either in the Board of Trade or under the Electricity Commissioners a new Department for the study, control, and encouragement of the use of water-power in Great Britain. Encouragement should include the grant of temporary financial assistance to promising power

schemes. This subject is to have fuller treatment in the final Report of the Committee.

In addition to new allocations the Water Commission should have power to revise existing allocations, including the compensation water already prescribed by Act of Parliament. Another duty would be the setting-up of local Rivers Boards to control individual rivers as a whole.

One further safeguard is suggested, namely, the appointment by the Commission of an advisory committee, or committees, consisting of "representatives of water undertakings and scientific institutions, consulting engineers, and other qualified persons." Presumably the services of these specialists are to be solicited gratuitously, for the Commission "also" ask to be empowered "to obtain and pay for professional advice in connection with their investigations."

Perhaps one might be inclined to doubt whether the Committee has always kept clearly in mind the essential distinction between scientific and technical advice; but in one respect at least the Report will be welcome to scientifically minded people. It places in the forefront of the duties of the Water Commissioners the investigation by scientific study of the actual water resources of the country and the strengthening of existing agencies by the creation of a hydrometric survey of rivers. One cannot help regretting that the various survey bodies are not united under one scientific Department, for it would be a natural development if the Department of Scientific and Industrial Research were to add to the care of the Geological Survey that of the Ordnance Survey, the Meteorological Office, and the proposed Hydrometric Survey. In these matters, however, simplification comes slowly, and it is a great matter to find a clear statement of the truth, which is not self-evident to all our legislators, that one must first ascertain what our resources are before we proceed to distribute them.

We have endeavoured to state the conclusions as briefly and simply as possible, but the Report goes into much detail and requires careful reading. The system suggested is, we believe, as simple and efficient as it could be made, bearing in mind the initial determination to work so far as possible through existing agencies. But it is open to doubt the wisdom of that determination and to ask whether the creation of a Central Department dealing with all water questions, and with water questions only, might not, after all, be a simpler, cheaper, and more efficient solution of the problem.

The Mathematician as Anatomist.

Department of Applied Statistics, University of London, University College: Drapers' Company Research Memoirs. Biometric Series, x.: A Study of the Long Bones of the English Skeleton. By Karl Pearson and Julia Bell. Text: Part i., The Femur. Chaps. i. to vi. Pp. v+224. Atlas: Part i., The Femur Pp. vii+plates lix+Tables of Measurements and Observations. (Cambridge: At the University Press, 1919.) Price, Text and Atlas, Part i., 30*s*. net.

Department of Applied Statistics, University of London, University College: Drapers' Company Research Memoirs. Biometric Series, xi.: A Study of the Long Bones of the English Skeleton. By Karl Pearson and Julia Bell. Text: Part i., Section ii., The Femur of Man, with special reference to other Primate Femora. Chaps. vii. to x., Appendices, Bibliography, and Indices. Pp. 225-539. Atlas: Part i., Section ii., The Femur of the Primates. Pp. vii+plates lx–ci+Tables of Femoral Measurements of the Primates. (Cambridge: At the University Press, 1919.) Price, Text and Atlas, Part i., Section ii., 40*s*. net.

IF in the rapid increase of knowledge at the present time there is a tendency for men to limit their labours more and more to one narrow field of investigation, there is also, we are glad to note, an opposite tendency leading men who have become eminent in their own particular subject to cross professional frontiers and to carry war, seldom peace, into neighbouring or even distant specialities. In the present two great publications, devoted chiefly to the human thigh-bone, containing more than a quarter of a million words, with tables which give the results of at least 70,000 measurements, and illustrated by 105 anatomical plates, we find Prof. Karl Pearson, the mathematician, definitely settling himself in the front bench of speculative anatomists. He cannot have expected a warm welcome in his new quarters, for there are few British anatomists who do not bear the mark of at least one of those biometrical brickbats at the throwing of which Prof. Pearson has manifested very considerable skill. They did not hurt any the less because they were meant kindly! In spite of all their scars, however, British anatomists—nay, anatomists of every country—who study these volumes will forget their past sores and be glad to welcome him to their membership for the great service he has rendered to their subject, not only in this, but also in previous memoirs.

To understand aright what has been accomplished in the memoir now under review one has to go back twenty-five years to 1895, when Prof. Pearson, then the occupant of the chair of applied mathematics at University College, London, showed how the mathematical theory of statistics could and should be applied to all the manifestations of life. He was the only man then in England to perceive that Francis Galton was a really great man, and that if the knowledge relating to man and to living things was to be placed on a sound foundation, it must be laid by an application and an amplification of the Galtonian methods. Anatomists had made a survey of the human body and recorded their experience by giving accurate descriptions of what they had seen and broad generalisations as to what they thought. Prof. Pearson realised, as Galton had done before him, that no progress could be made in our knowledge of populations, races, or species until accurate standard methods of measurements had been applied to great numbers of individuals, and hence the first task which faced him, in building up a biometrical school, was the gathering of data to which statistical methods could be applied. Fortunately Sir George Thane, when professor of anatomy at University College, had had the foresight to store in his department great assemblages of human bones recovered from burial grounds in the East End of London—presumably remains of seventeenth-century Londoners who had died of the plague. This material became a treasure trove for the growing biometrical school.

Prof. Pearson's methods were applied to the skulls by the late Dr. W. R. Macdonald, and for the first time we had given to us standard data relating to the skull of the Englishman. Skulls have always been a favourite means for the study of racial characters, but Prof. Pearson wished to show that other bones had also their racial values, and by 1907 he was in a position, with the assistance of Miss Julia Bell, to commence his investigation of the thigh-bone.

Prof. Pearson had in the East London collection about 800 examples of this bone—each of which was examined, and in almost every instance measurements were made and estimates formed relating to eighty characters—in some examples to as many as a hundred—in order to establish the prevailing features of the thigh-bone of English men and women. He had to standardise old methods of making measurements and indices and to invent many new ones. In the course of his work he has brought to light many important facts which are new to anatomists. From this first phase of his investigation he was led, very naturally, to a second—to see how the English thigh-bone compared with that of Continental peoples. He had to search foreign records, and found them almost as barren of accurate details as those at home, but we cannot help noting his leniency towards the shortcomings of anatomists who live beyond the shores of England. Then followed in due course a third step—a comparison of the thigh-bone of the European with that of other races of the world—and a fourth—a comparison of the thigh-bone of modern man with that of ancient and extinct races of mankind. A fifth extension of his original aim was a comparison of the human femur with that of other members of the Primate class—the gorilla, the chimpanzee, the orang (the great anthropoids), the gibbon (or small anthropoid), the monkeys of the Old and of the New Worlds, and lastly with the lowest of Primate forms—the Lemuroids, including Tarsius. Then came a sixth extension—a study and comparison of the thigh-bones of extinct apes and Lemuroids. Finally, on the evidence he had thus accumulated from an intensive study of the thigh-bone, we have the construction of a pedigree or lineage of their owners—a pedigree which gives us the conception he has formed of man's evolutionary history and of man's relationship to the higher members of the animal kingdom.

By this natural sequence of inquiries the professor of mathematics has become an exponent of human phylogenetics. Setting out in 1907 with the intention of examining the femur of the Londoner, he ended in 1919 with a survey of the world of Primates.

Those who have had experience in arranging the members of a group of plants or animals—in conformity with their natural affinities—in a scheme which will express their evolutionary relationships are well aware that diverse, even contradictory, results are obtained, according to the system of parts used in framing the scheme of classification. If we arrange the Primates by grouping them according to the anatomical characters of their teeth, we get one result; if by their brains and nervous system, a second and very different grouping; if by their digestive system, a third; if by their reproductive system, a fourth, and so on. All the systems have to be taken into account, and to some, such as the brain, much more weight must be given than to others. In the most perfect scheme of classification there are always blemishes; the evidence of one system will be found to contradict or be at variance with that of another.

There need be no surprise at this variance of evidence; it should be so if heredity works in a Mendelian way. If we confine our attention, in

framing a pedigree, to the parts of one system, more particularly to a single element of one system, as Prof. Pearson has done, there is a great risk of obtaining a purely artificial scheme of arrangement. If we use the thigh-bone alone, our classification of the Primates will serve to show only the evolution of their locomotory systems.

We are not forgetful that the discovery of a single fossil thigh-bone may be the sole basis on which we have to reconstruct an extinct form of man or ape. In such an event this memoir would be invaluable, for it gives us, for the first time, the basis on which a rational prophecy can be framed. There is a case in point which is very elaborately dealt with by Prof. Pearson—the thigh-bone of Pithecanthropus. He has applied more accurate and more elaborate tests to the anatomical characters of this bone than has hitherto been the case, and comes to the conclusion, as the majority of anatomists have already done, that in no essential point does it differ from that of modern man. And yet the skull assigned to this primitive humanoid form is almost as much that of an ape as of a man. Prof. Pearson is too cautious a man of science to deny the possibility of a being having at the same time an almost perfect human femur and a skull and brain which are non-human, but he is clearly more than sceptical, for in his scheme of classification Pithecanthropus must be given a place amongst races of modern man. Even when he has given us, as he has promised—and it is sincerely to be hoped he will be able to carry it out—his programme of research—the correlationship of the thigh-bone to all the other bones of the body and their correlationships to the jaws and cranium—there will still remain the infinitely more difficult task of stating in mathematical terms the correlationship of one system to another, such as that of the nervous to the digestive system, or of the respiratory to the reproductive, circulatory, and other systems. For some time, it is clear, we must depend, as in the past, on the somewhat crude methods of anatomical appreciation and analysis.

We have already told how the principal author of this monograph was led, during the latter part of the twelve years he devoted to a study of the femur, to ascertain what light his results shed on the evolutionary histories of mankind, the anthropoid apes, monkeys, and lemurs. It is true that his method of comparison sometimes leads him to quite surprising situations—of the humour of which he is perfectly aware—as when man and the pig find themselves the closest of allies as regards the diameters of their femoral shafts, or when the Old World monkeys find themselves cheek by jowl with man because of the equality of length in their femoral condyles. But on the whole his results and deductions must be regarded as helpful and trustworthy. It so happens that the writer of this review has, these thirty years past, been collecting data from all the systems of the Primate body (see NATURE, 1911, vol. lxxxv., p. 508), and has from time to time assorted his observations to see how far a scheme of Primate evolution could be framed which would give a coherent explanation of the distribution of anatomical characters such as is now seen in the bodies of man, the anthropoid apes, and the monkeys of the Old and New Worlds. The results which have been reached by Prof. Pearson and the reviewer are, in the main, in harmony. The mathematical anatomist insists upon an anthropoid or troglodytic link in man's lineage; he claims to have reinstated the great anthropoid or troglodyte as a necessary stage in man's ancestry; but he will find that very few anatomists who have given this problem due thought have dismissed the anthropoid apes from the place given to them by Huxley. Prof. Pearson gives Tarsius a remote place in his scheme of human evolution. He is right, too, in dismissing the present-day gibbon from man's family tree, but altogether wrong if he supposes that the hylobatian stock from which the modern gibbon (highly specialised so far as limbs are concerned) arose plays no part in man's lineage. He is right, too, in concluding that the gibbon has no claim to be brigaded with the great anthropoids —the gorilla, chimpanzee, and orang. In their essential structure the gibbons form a separate group, one which serves to link together—or at least to bridge the gaps between—the monkeys of the Old and New Worlds and the great anthropoids. They are the essential link between monkeys and anthropoids. The femoral characters of the gibbon give a somewhat misleading indication of its true place in the phylum of the higher Primates.

As a common ancestor of the human and great anthropoid group—the pre-troglodyte in man's lineage—Prof. Pearson postulates a "Protsimio-human" Primate form, which he believes will turn out to be more human than anthropoid, a mathematical deduction with which few naturalists will agree. On the other hand, certain inferences made regarding the status and relationship of early races of man in Europe, founded entirely on the characters of their thigh-bones, are particularly worthy of attention. There has been much speculation regarding the existence of negroids in southern Europe in late Pleistocene times, founded on the discovery of remains of two Grimaldi indi-

viduals in a cave near Mentone. From a study of their skulls the reviewer came to the conclusion that they had nothing of the African negro in them, but that they were of the Cromagnon race, a conclusion which Prof. Pearson has reached independently from a study of their thigh-bones. He is uncertain of the relationship of Neanderthal and of Cromagnon man to modern races of mankind—uncertain as to whether these two types of ancient Europeans should figure as stages, or links, in the chain of modern man's evolution, or whether they really represent branches which have sprung from that stem. The evidence of their skulls and teeth leaves modern anatomists in little doubt as to their true relationships; Neanderthal man represents the terminal stage of a side branch, whereas Cromagnon man is but one of the numerous varieties of modern man. One other point is to be noted: in surveying the evolutionary evidence yielded by a single bone the same discordant array of indications is found as when all the systems of the body are studied; the final result has to be obtained by an exercise of judgment on the part of the classifier.

It is a matter of everyday observation that no two people walk exactly alike; there is the same infinite variety in the human gait as is found in the human face. Women have their own particular kind of progression; not one of us uses the right limb in exactly the same way as the left; the left foot is more frequently inturned to a greater degree than is the right. If, as medical men believe, bone-cells are peculiarly sensitive and responsive to the muscular and other stresses which are brought to bear on them, then there ought to be just that range of variation of form in the thigh-bone which this monograph demonstrates to exist. A functional explanation of the structural variation of the femur is one which Prof. Pearson is not prepared to entertain, and unfortunately medical men have as yet neglected, or almost neglected, the study of the living femur, and are therefore unable to say whether or not the anatomical forms of the femur are correlated to certain peculiarities of gait. The improvement in our means of examining the anatomy of the thigh-bone in the living by the aid of X-rays is likely to fill up this blank in our knowledge, and at the same time to offer a rational explanation of many puzzling features noted and estimated by Prof. Pearson and his collaborator. A study of the manner of progression of anthropoids in their natural habitats will help to show how closely form and function are correlated. In the orang, for instance, the hind limbs are reduced to mere grasping organs; in it and in the gibbon the swinging arms are the chief organs of progression. In the reviewer's opinion all measurements and calculations should be made, so far as is practicable, not only to indicate the degree and kind of racial characteristics, but also to express degrees and kinds of function. Indices should be of such a nature as to convey to the student a precise conception of the degree and kind of function.

This great memoir opens up a prospect which may well appal the heart of the stoutest anatomist. Here we have two parts, running to 539 pages, each page containing on an average more than 500 words, devoted to the subject which the authors speak of as femoralogy and the special students of which are called femoralogists, with the promise of a third part. When the examination of the human skeleton is completed on a corresponding scale we shall have an immense library. We may not like the prospect, but is there any option if our knowledge of mankind is to be based on a foundation which will last? The reviewer does not think there is any other way, and feels sure that the time will certainly come, if it has not already come, when anatomists the world over will acknowledge the courage, industry, and prescience of the English school of biometrics and of its founder. It would be a set-back to the progress of our knowledge of mankind were Prof. Pearson's projected programme to be in any way curtailed by a lack of financial assistance. A. KEITH.

The Theoretic Basis of Psychotherapy.

The New Psychology and its Relation to Life. By A. G. Tansley. Pp. 283. (London: George Allen and Unwin, Ltd., 1920.) Price 10*s.* 6*d.* net.

ABOUT fifteen years ago Prof. Scripture, of Yale, published his book upon "The New Psychology." The psychology which was "new" then was experimental psychology; now the new psychology is something very different—the study of the non-rational processes of the human mind. Most of the material of Mr. Tansley's book consists in theories which are contained in the works of Prof. Freud, of Vienna; of Dr. Jung, of Zurich; and of Mr. William McDougall, who is just now leaving Oxford to settle at Harvard. The work of these three researchers has achieved world-wide renown; Mr. Tansley has done a good service in presenting some important elements of them in a compact and readable form. Mr. McDougall's books are accessible enough, but the views of the two Continental savants are scattered through various publications in a way which is rather baffling to the English reader. With

the help of Mr. Tansley anyone can now make himself acquainted with the main points at issue.

The work of Freud and Jung deals mainly with the sub-conscious, that mysterious twilight region of the mind whence spring most of our deepest and strongest motives. The key which Freud has used to unlock its secrets is sex. He lays stress upon the immature sex-experience of young children and upon the repressed sexual desires of adult life which show themselves in dreams and in lapses of memory and behaviour. In this way he explains not merely the unusual phenomena of hysteria, but also the mental strains and stresses which trouble the peace of ordinary sane men. Dr. Jung, on the other hand, takes a wider view; he argues that not only sex, but also every strong natural human interest—the desire for self-preservation, for example—may be the cause of mental conflicts and nervous disorders. His view has been strikingly confirmed by the experience of the physicians who have treated the complicated war-neuroses which are familiar to the public under the term of "shell-shock." It is another side of the sub-conscious that has engaged the attention of Mr. McDougall. He has written more upon our instinctive life and shown how much of the experience which seems to us distinctively human is really based upon tendencies that are shared with the animals below us. He has done a great work in analysing our various instincts and in showing how they influence our conduct and our emotional life.

The main reason why the new psychology has so greatly impressed popular imagination is that most excellent results have been produced by it in the treatment of nervous disorders. The early workers in this field were men who were either practising physicians, or closely in touch with medicine. As soon as they formed a theory they proceeded at once to put it to the test of practice. Extraordinary cures have been performed by working upon the assumption that the trouble in the patient is of mental origin, and that the bodily symptoms are merely the physical expression of mental strain. In psychotherapy, as in medicine generally, our knowledge of detail and of derivative facts far exceeds our knowledge of fundamental principles. We know, for example, that if the physician is able to discover the nature of a hidden mental conflict which is troubling the patient, and can talk and reason with him about it, the symptoms are usually relieved. This process is technically termed "abreaction," and the real efficacy of it is attested by scores of incontestable cures.

This being so, it is easy to explain why Mr. Tansley's book is most satisfactory when he is dealing with such matters as the interpretation of dreams, the "rationalisations" by which men try to justify conduct which is really prompted by non-rational motives, and the great psychic complexes which correspond to the main instincts of man. And we can explain why the book is less satisfactory in the general theoretical chapters with which it opens. Mr. Tansley has done his best to combine "new" psychological theories from Freud, Jung, and McDougall into a consistent whole. The result is not very clear or convincing. But perhaps in the present state of our knowledge we could scarcely look for greater success.

H. S.

Industrial Research.

The Organisation of Industrial Scientific Research. By Dr. C. E. Kenneth Mees. Pp. ix+175. (New York and London: McGraw-Hill Book Co., Inc., 1920.) Price 12s.

THE author of this book is a distinguished worker in the branch of science with which he is associated, and his experience as the director of a large industrial research organisation has been such as to warrant careful consideration of his views. The book is mainly intended for manufacturers who, while convinced of the need for research in their industries, have had no occasion to consider in detail the planning and administration of a works research department. Many scientific workers will also welcome an opportunity of acquainting themselves further with the broad questions of research policy and organisation in industry, which the individual engaged on a specific task often fails to see in correct perspective. The scope of the book and the sequence of chapters are admirable. Consideration is given to various types of research laboratories, to the development of co-operative research, and particularly to the internal organisation and staffing of the works research laboratory, together with its relation to the other parts of the factory. Some general details are also given relating to the design and equipment of the laboratory, and a comprehensive bibliography is attached.

The classification of research laboratories largely resolves itself into a list of the various agencies by which the laboratories are financially maintained. To avoid the obvious disadvantages of such a grouping, the author distinguishes between "convergent" and "divergent" laboratories, depending on whether varied problems and phenomena converging on a common object are studied, such, for instance, as at the pottery school at Stoke-on-Trent or at the laboratory for glass technology at Sheffield, or whether a wider field is covered having no particular common

feature, such as at the National Physical Laboratory or at a laboratory serving the interests of a group of works producing many kinds of manufactured articles.

Criticising the research associations developed in this country, the author deprecates the degree of control remaining in the hands of the Research Department, the character of the *personnel* of the Advisory Council and its committees, and the policy of secrecy which is fostered by a research association comprising a group of manufacturers in one industry; and considers the difficulty of determining the choice of researches and the disposal of results to be serious. Many people, however, will not display any particular enthusiasm for the author's alternative proposal, a co-operative laboratory conducted by an association of users. It may be admitted that users have a common interest, but this is less clearly defined and much more difficult to focus on one line of research than that of an association of producers. Users also have less experience in the production of the material they employ, and in industry it is highly desirable to make use of existing knowledge as a basis for research. The author may not be aware that, in some cases at least, British research associations are dual in character, comprising both producers and consumers, this probably being an ideal combination.

It is important to note that the author considers it undesirable to divorce a works research department from works problems, and the success of notable instances to the contrary should not obscure the principle.

Many readers will doubtless wish that the author had gone further into detail than is the case in many chapters. The economic and social benefits of research should perhaps not have been taken for granted, and the question of the co-ordination of research and the collection and distribution of scientific intelligence could have been dealt with to advantage. In general, however, the book bears the marks of experience throughout, and will well repay perusal.

A. P. M. FLEMING.

Science and Crime.

Legal Chemistry and Scientific Criminal Investigation. By A. Lucas. Pp. viii+181. (London: Edward Arnold, 1920.) Price 10*s*. 6*d*. net.

THERE are numerous text-books on the subject of forensic medicine, but, with the exception of works on toxicology, there are very few which deal with analogous problems to the investigation of which chemistry is applicable. This little book makes no pretension to being a complete treatise on forensic chemistry, and to this extent its title is misleading, for it consists largely of notes on the cases which have come within the author's experience, together with a few general remarks on the methods of dealing with exhibits and presenting the evidence in such cases.

As director of the Government laboratory in a country such as Egypt, where frauds of all kinds appear to be exceptionally numerous, the author has had the advantage of applying the methods described in various journals in a great number of cases, and of noting their deficiencies, and he gives particulars of these cases arranged alphabetically under the headings of the different subjects.

As a rule, original methods have not been devised, but some of the sections give interesting details of the author's investigation in connection with special subjects. For example, referring to human hair, he shows that it is doubtful whether the alleged change in the colour of the hair to red has ever been caused by the Egyptian method of embalming. Another novel point of chemical interest is that in no instance has pitch or bitumen been found in the pitch-like material used in preserving human mummies, the material examined invariably consisting of resins or gums which have become naturally blackened by age.

From the point of view of the practical chemist, the most useful section is that dealing with the examination of documents, in which questions connected with the composition of paper and inks are dealt with at some length. In one land case, it was found that out of 168 documents no fewer than 163 were forgeries, the frauds ranging from simple alterations of names to the elaborate fabrication of documents by joining parts of other documents, and concealing mutilations by partly scorching the paper. In this connection the author lays stress upon the importance of knowing the dates of changes in the methods of manufacturing paper and the like.

As carbon ink is still frequently used in Egypt for title deeds of land, the author has had the exceptional opportunity of studying modern documents written in ink similar to that used prior to the invention of iron gall inks, and he gives interesting particulars of his observations. Contrary to the commonly accepted belief, the carbon inks on several of the older Arabic documents between A.D. 1677 and 1871 were partly brown, and the same thing was noted on still earlier manuscripts dating back to A.D. 622. Hence the conclusion is drawn that it must be regarded as proved that carbon inks which were originally black may become brown with age.

The questions of secret writing and its develop-

ment, the imitation of seal impressions, the forgery of postage stamps, and the examination of handwriting are also briefly touched upon in this section, whilst there is a cognate section upon the detection of robbery from letters and parcels in transit.

Other subjects which are discussed include the examination of dust and stains, the development of finger-prints, the investigation of the cause of fires and of damage to crops, and the examination of fibres, ropes, and clothing. In each case references to literature on the subject are appended, and illustrative cases usually given.

Regarded as a whole, the book should be welcomed by every chemist whose work is likely to include any problems in which legal questions are involved, and it might well be made the nucleus of a more comprehensive work on forensic chemistry. It is sometimes urged against the publication of details of scientific methods as applied to the detection of crime, such as are given here, that it is dangerous to provide prospective criminals with information in a convenient form for reference; but this objection applies with more cogency to the publication of the scientific methods of combating the adulteration of food. The adulterator is frequently waiting to be made acquainted with the scientific drawbacks of his methods, whereas the persons who commit other forms of fraud are nearly always without scientific training and, if they were to attempt to avoid one scientific pitfall, would be almost certain to fall into another. C. A. M.

Our Bookshelf.

Optical Projection. By Lewis Wright. Fifth edition, rewritten and brought up to date by Russell S. Wright. (In two parts.) Part i., *The Projection of Lantern Slides.* Pp. viii+87. (London: Longmans, Green, and Co., 1920.) Price 4*s.* 6*d.* net.

THIS completely revised edition of Mr. Lewis Wright's book is very welcome. We are glad to see that the oil-lantern, which is so handy in small class-rooms and in the huts of camps, is still regarded as a possible projector. It may be mentioned that if this lantern is filled for each occasion, and set up lighted in an adjacent room, or, better still, in the school-yard, for forty minutes or so before the lecture, all risk of producing offensive fumes will be avoided. In regard to screens for such class-rooms, may we add that a square of mounted diagram-paper, which is made 5 ft. wide, gives an excellent surface, and can be kept rolled up and fixed with large drawing-pins as required? Lastly, when Mr. R. S. Wright gives suggestions as to flash-signals, should he even tolerate the "next slide" system of communication with the operator? The recently introduced silent wave of the pointer has escaped mention in this useful treatise. G. A. J. C.

Elementary Agricultural Chemistry: A Handbook for Junior Agricultural Students and Farmers. By Herbert Ingle. Third edition, revised. (Griffin's Technological Handbooks.) Pp. ix +250. (London: Charles Griffin and Co., Ltd., 1920.) Price 5*s.*

THERE are no essential differences between this and the second edition of Mr. Ingle's book. The volume provides an excellent introduction to its subject in a form which should be intelligible to the practical agriculturist as well as to the scientific student. It contains a number of interesting and useful tables, and on account of its very reasonable price it should be popular with students of agriculture. Although described on the cover as "A Practical Handbook," it contains no account of experiments or methods of analysis, but these would no doubt have increased the size of the book beyond the limits desired.

Luck, or Cunning, as the Main Means of Organic Modification? An Attempt to Throw Additional Light upon Darwin's Theory of Natural Selection. By Samuel Butler. Second edition, re-set, with author's corrections and additions to index. Pp. 282. (London: A. C. Fifield, 1920.) Price 8*s.* 6*d.* net.

THIS is a reprint of the first edition published in 1886. The only important changes are in the index, which has been considerably enlarged by additions made from notes by the author in a copy of the first edition. As is announced in the introduction, the book is written round Samuel Butler's favourite theories, "the substantial identity between heredity and memory," and "the re-introduction of design into organic development."

Notes on Chemical Research: An Account of Certain Conditions which apply to Original Investigation. By W. P. Dreaper. Second edition. (Text-books of Chemical Research and Engineering.) Pp. xv+195. (London: J. and A. Churchill, 1920.) Price 7*s.* 6*d.* net.

THE first edition of this stimulating work was reviewed in NATURE for February 6, 1913. The new edition is divided into two portions, the first dealing with the history and method of research, and the second with modern works practice. A chapter in the latter portion is given up to the consideration of the training desirable for a research student. An index would have been helpful.

Spiritual Pluralism and Recent Philosophy. By C. A. Richardson. Pp. xxi+335. (Cambridge: At the University Press, 1919.) Price 14*s.* net.

THE author examines the Weber-Fechner law of sensation and shows that "unperceived sense-data," such as are sometimes deduced from it, are not logically admissible. He expresses spiritual

pluralism as the assumption that our sense-perceptions are due to other "subjects of experience" of a non-material nature, and akin to our own subjective self. Guided by this principle, he discusses determinism and immortality, the relation of mind and body, and certain abnormal phenomena usually called "spiritualistic."

Unconscious Memory. By Samuel Butler. Third edition, entirely reset; with an Introduction and Postscript by Prof. Marcus Hartog. Pp. xxxix + 186. (London: A. C. Fifield, 1920.) Price 8*s.* 6*d.* net.

THE first edition of this work was reviewed in NATURE for January 27, 1881. The second edition, noticed in NATURE for November 3, 1910, contained an introduction by Prof. Marcus Hartog, giving an outline of Samuel Butler's works and discussing their value to science. In the present edition Prof. Hartog has appended to his introduction a postscript in which he sets forth, briefly, the position of Samuel Butler's biological works in modern science.

Wild Fruits and How to Know Them. By Dr. S. C. Johnson. Pp. xi + 132. (London: Holden and Hardingham, Ltd., n.d.) Price 1*s.* net.

A BRIEF description of most of the trees and shrubs found on the English countryside is given, special attention being paid to the forms of inflorescences and fruits. Identification of specimens is greatly simplified by the large number of sketches, showing both foliage and fruit, which are included. The last chapter is devoted to the commoner plants and weeds which have conspicuous fruits.

Silver: Its Intimate Association with the Daily Life of Man. By Benjamin White. (Pitman's Common Commodities and Industries.) Pp. xi + 144. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2*s.* 6*d.* net.

THIS volume is more concerned with the statistics and economics of silver than with technology, although an interesting account of the extraction, purification, and utilisation of silver is given. There are many useful tables. An interesting chapter deals with "The Evolution of British Coinage." The book is addressed to the general reader, but contains much of service to teachers and students.

The Identification of Organic Compounds. By the late Dr. G. B. Neave and Prof. I. M. Heilbron. Second edition. Pp. viii + 88. (London: Constable and Co., Ltd., 1920.) Price 4*s.* 6*d.* net.

THE second edition of this useful manual has undergone practically no alteration. It is one of the best books of its kind, and contains a large amount of information in a handy and compact form. We have no doubt that it will continue to find favour among students and teachers of chemistry.

Gold: Its Place in the Economy of Mankind. By Benjamin White. (Pitman's Common Commodities and Industries.) Pp. xi + 130. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 3*s.* net.

THE steps by which gold has acquired its high value, and its past history with regard to production and uses, are described. The last portion of the book is devoted to a review of the gold stocks in the world and their movements before and during the Great War. A number of tables is included, showing the amount and value of gold in use in various countries; these should be of interest to students of commercial geography and economics.

Pastimes for the Nature Lover. By Dr. S. C. Johnson. Pp. 136. (London: Holden and Hardingham, Ltd., n.d.) Price 1*s.* net.

SOME of the plants and smaller animals commonly found in this country are described, and methods of preserving them or of studying their habits, as the case may be, are given. Silkworms and Nature photography are also mentioned. The book would be of use to young collectors.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

University Grants.

I AGREE with Sir Michael Sadler in thinking that the article on university grants in NATURE of August 5 is very opportune, and I concur completely in all that he says on the subject in the issue for August 12. It is not necessary for me to repeat the arguments and the statements so briefly and emphatically expressed by the Vice-Chancellor of the University of Leeds, because I feel sure that everyone with a competent knowledge of the situation in the modern universities would agree that Sir Michael Sadler has by no means understated the gravity of the crisis with which the universities are faced.

At Birmingham, as at Leeds, we have been rigidly economical in our expenditure. We know that we are doing work the value of which is appreciated by our students and the community of the Midlands whom we endeavour to serve. But unless large new grants are forthcoming it will be impossible for us not only to continue to meet those needs, but also to maintain the standard of work in the various departments.

To what Sir Michael Sadler has said I would add only two points:

(1) Unless the stipends of the non-professorial staffs of the universities are placed on something like equality with those obtaining for skilled intellectual work elsewhere, *e.g.* in the Government service or in the service of the great municipalities, it will be impossible to obtain or retain the men and women with the requisite qualifications for university work; and it is from the members of the non-professorial

staffs, when they have been trained in the universities, that the universities must later look for filling the professorships. A decrease, therefore, in the number and the quality of the non-professorial staffs of the universities means ultimately a decrease in the number and quality of the professors throughout the country. University teachers, particularly of professorial status, cannot be improvised or provided at a moment's notice. Competent professors are the result of attracting the requisite ability to the service of the universities in the junior grades and providing those junior grades with the opportunities for training in teaching and in research until they have reached the standard expected for professorial purposes. Unless, therefore, the universities are properly staffed, in a few years' time the whole standard of teaching and of research and of knowledge throughout the universities will inevitably drop; and it is desirable to remember that on the maintenance of the standards of the professoriate the training of the non-professorial staff largely depends.

Serious as is the situation to-day, its full meaning will not be apparent until some years hence, and it will then be impossible to make good what can be made good now, if we are not penny wise and pound foolish.

(2) Inadequate staffs, inadequate teaching, and overworked professors mean a drop in the quality of the students turned out by the universities. It is to the university-trained student that the Government, the municipalities, the schools, and the whole commerce and industry of the country must look for its *personnel*. If the universities are not doing their work up to the standard required, it is not the universities ultimately which will suffer most, but the whole nation. We shall be beaten as a nation because we shall be inferior as a nation.

The policy of the Government and of the local education authorities at present is to encourage, and rightly to encourage, the extension and the elevation of secondary schools in order to increase both the number of boys and girls to be kept on until they are eighteen years of age, and the number of boys and girls who will be fit to profit by a university education. What is the use of spending millions on adding to and improving the secondary schools throughout the country if the universities, which are the apex of this educational system, are to be starved? The secondary schools will be pouring out students which the universities will not be able to take; or, if they do take them, will not be able to give them a proper university education under proper teachers. Because you refuse to spend three millions, you will waste twenty or thirty millions.

Research in the universities, owing to the present congestion and inadequacy in numbers of the staff, is at present at a standstill; and unless steps are taken *now* to provide competent researchers, as well as a proper organisation and opportunities for research, the advancement of knowledge in Great Britain will come to an end. Organised research cannot be carried on anywhere except in a properly equipped university; and where industrial firms are carrying it on in a few specialised branches of industrial science from their own resources, they rely upon being provided from the universities with men and women fit to do the research required. It is not the business of, nor is it possible for, great firms to do the work of the universities in all the departments of knowledge.

The Government and the nation must make up their minds not so much as to whether the universities are to continue as to seeing that the universities are really universities and doing university work. The funds cannot be provided from the tuition fees of the students. Seventy-five per cent. of the cost of maintaining a university must be provided from other sources than those of fees. I agree, therefore, with Sir Michael Sadler that while we welcome the additional half-million promised twelve months hence, another million and a half at least are required in order that the universities may be maintained on an adequate basis.

At Birmingham, as at Leeds, we need another 60,000*l*. a year in income in order to meet absolutely necessary expenditure. C. GRANT ROBERTSON.

The University, Birmingham, August 13.

Aerial Navigation and Meteorology.

PROF. VAN EVERDINGEN'S outspoken criticism in NATURE of July 22, p. 637, of the meteorological arrangements outlined in Annexe G of the Convention for International Air Navigation is very welcome. Prior to the war the International Meteorological Committee met every three years in friendly gatherings for social intercourse and the transaction of business. Broadly speaking, the difficulties of the members were in obtaining sufficient funds to enable them, in their respective services, to achieve the ends upon which they were agreed rather than in securing agreement on the desiderata for international exchange. Now that the former difficulties have been largely met as a result of the achievements of meteorology in the war, it would be calamitous if meteorologists failed to overcome the latter, and disturbed the unity of European meteorology at a time when their efforts ought to be directed to achieving unity in world-meteorology.

I am convinced that the scheme of Annexe G is a good one, and that a frank discussion of the details with the Continental meteorologists who were not present at the Peace Conference in Paris in May, 1919, would lead to the general adoption of the scheme with the slight modifications which experience of its working has indicated.

Prof. van Everdingen states that Annexe G was discussed at the meeting in London of members of the pre-war International Meteorological Committee. He has been misinformed. Permission to put Annexe G before that meeting was definitely refused. If such a discussion had been permissible, it would probably have removed many misapprehensions.

To take some examples from Prof. van Everdingen's article:

(1) He objects that in Appendix III. (apparently a misprint for Appendix I.) he finds "wind, temperature, and humidity in the upper air as additional and facultative." By "facultative" he means "optional." But Annexe G neither says nor implies that such reports are "optional." The exact words are: "Reports will give information on [wind, etc.], and also on upper air-currents and upper air-temperature and humidity from stations where facilities are available for observation." All standard meteorological stations are able to report wind, pressure, temperature, and weather phenomena three or four times daily all the year round; but only specially equipped stations can report upper air-currents, temperature, and humidity, and no station could in 1919, or can now, report upper-air information with the same frequency and regularity as standard stations report surface observations.

(2) Prof. van Everdingen states that the use of the telegraphic scale 1–72 means that an accuracy of 5° is claimed for surface wind direction. That is not so. In the past a scale of 1–32 has been nominally used (actually the

odd numbers are usually not utilised), but no one thinks that an accuracy of $11\frac{1}{4}^{\circ}$ is thereby claimed, and everyone knows that the exposure of the anemometer and the turbulence of the wind cause larger variations with space and time than $11\frac{1}{4}^{\circ}$. The scale 1–72 was adopted for the following reasons: Nearly all the observations of wind in the upper air are made by theodolites graduated in degrees and read to tenths of a degree (or exceptionally to minutes). The direction of the upper wind is obtained in degrees. Division of the number so obtained by 5 leads to the scale 1–72. It is much simpler than division by $11\frac{1}{4}$, which would lead to the scale 1–32. Moreover, the variation of wind direction with height cannot be indicated with sufficient precision by a scale 1–32. Also, the general practice in scientific work is to specify directions in degrees, and the practice is extending both at sea and in the air. The scale 1–72 is the most precise two-figure scale which is readily converted into degrees.

Whatever method is used for obtaining wind direction at the surface, the result can be telegraphed in the scale 1–72 without difficulty; if only the eight principal directions (N., N.E., E., etc.) are used, then only the corresponding numbers of the scale (72, 9, 18, etc.) will be used.

(3) Prof. van Everdingen objects to the use of two figures for reporting "weather." The need for an extension of the existing one-figure code has been apparent for a long time. A meteorologist at headquarters requires from a reporting station sufficient information to enable him to say with precision and certainty what the weather was at the station at the time of report. With the pre-war code for international exchange this was not done. A few drops of rain or a little drizzle were reported by the same figure as the most torrential downpour. A few flakes of snow or some fine ice-crystals were reported by the same figure as the heaviest snowstorm. No figure was provided for hail or sleet, and no indication given of the thickness of a fog (in past weather). A sky nearly covered with thin, white clouds at 20,000 ft. or 30,000 ft. was described by the same figure as the darkest, gloomiest day of the year. All this was due to the restriction of the pre-war code to one figure. It was not due to failure on the part of pre-war meteorologists to recognise the phenomena which ought to be recorded and the need for differentiation of intensity. *Practically the whole of the phenomena for which provision is made in the ninety-five figures of the code of Annexe G are included in the "hydrometeors" for which provision was made in Appendix I. of the fourth meeting of the International Meteorological Congress at Vienna in* 1874. Annexe G merely makes provision for reporting by telegram, at the time when it is of direct use, the information which the Congress at Vienna arranged should be written down and reported in *monthly returns* for later scientific investigation. As to the observer being puzzled, there will always be some occasions when he is required to use intelligence in deciding which number to select, whether the single-figure pre-war code is in use or the fuller two-figure code. The difficulty is minimised for him in Annexe G by arranging that all occasions on which precipitation occurs shall be reported by a number greater than 50. We have not found in actual practice the troubles which Prof. van Everdingen fears.

The severest criticism is directed against the inclusion of detailed codes in the Convention. Holland signed the International Convention for the Safety of Life at Sea in 1914; that Convention included detailed codes for meteorological reports. Meteorology is more vital to the safety of life in the air than even ice reports to the safety of life at sea. The latter were made obligatory in 1914.

No one questions the *competence* of the International Meteorological Committee to fix the details of a code. That Committee must be in substantial agreement on the details of any code before it can be made generally obligatory. But at present the urgent need is for the trial of a scheme by the nations of Western Europe which is capable of being extended to the whole globe. The scheme of Annexe G is the only one in the field which provides both the general forms for meteorological messages and the detailed specifications necessary for reports to be made and interpreted in the confidence that their meaning is clear and definite, and that the information which they contain meets the present needs of an organised meteorological service. E. GOLD.

8 Hurst Close, N.W.4, July 25.

(1) COL. GOLD is not too well informed about the history of the International Meteorological Committee. The introduction of improvements in the reports and codes has often given rise to animated discussions; for example, when barometric tendency was introduced. It is true that the opponents remained friends, and that the minority co-operated in carrying out the resolutions, but that was a reason not to insist upon the introduction of a resolution which had been adopted by 7 votes against 6.

(2) There is at present no unity in European meteorology; it is no use to quarrel about who disturbed it; discussion of *various systems* by a competent body is the only way to restore it. I am very glad that the British weather reports for aerial navigation have modified already part of the codes of Annexe G. This certainly is a step towards reconciliation.

(3) The minutes of the meeting of members of the pre-war International Meteorological Committee held in London in July, 1919, at which both Col. Gold and I were present, contain a collection of codes almost identical with that of Annexe G. Col. Gold is right when he says that Annexe G was not discussed then, but that makes very little difference.

(4) Every standard station can report cloud motion or pilot-balloon observations. I am glad to state that cloud motion has now been introduced in regular British reports.

(5) The reading of the theodolite is accurate enough, but the direction of upper wind derived from the results is, in general, not accurate to less than 10°. A scale 1–36 is used in Holland and elsewhere. For scientific use a more accurate indication may be useful; for practical purposes it is useless.

(6) I only object to the way in which the two figures are combined for reporting weather; extension of the space for description of weather is welcome.

(7) My remarks referring to numbers to be used by observers in reporting phenomena are based on the practice *we* actually have had with the British reports.

(8) Annexe G can have its trial at the present moment if the Powers who signed it care. There are several other systems and codes being tried by various countries, and when these have had their course we shall be in a better position to decide what the present needs of an organised meteorological service are and how they can be met. E. VAN EVERDINGEN.

Koninklijk Nederlandsch Meteorologisch Instituut, De Bilt, August 9.

Growth of Waves.

THERE has always been some difficulty in accounting for the growth of waves under the action of wind. Do the individual waves grow in length, or does the wind raise waves of all lengths which separate in virtue of the dependence of wave-velocity on wave-length? The late Lord Rayleigh was in favour of the latter hypothesis, but I believe that the true explanation is that the waves do not increase in length unless they are breaking.

The excess of energy supplied by the wind to the water beyond that which can be carried in an unbroken wave is expended partly in causing local turbulence (ultimately converted into heat) and partly in producing a surface current in the direction of the travel of the wave. In effect, this surface current increases the wave-velocity; and since the addition to the current by each wave depends on the time for which that wave has been in existence, the waves first formed will, after the lapse of time, be travelling faster than the more recently formed waves which follow. Thus if waves are set up by wind on a previously calm water-surface, the wave-length will continuously increase from windward to leeward.

I have made some rough observations on a pond something like 1000 ft. in length, and found that in a brisk breeze the waves formed at the windward end showed as ripples of a few inches from crest to crest, while at or near the leeward margin the wave-length was about 2 ft. If it is assumed that the wave-length increases regularly, there would be about a thousand crests in the length of the pond, and the gain in length from wave to wave would be about 1/1000th of the mean wave-length. All the waves from the least to the greatest were in a breaking condition. The ripples did not show any foam at their crests, but it was clear from their shape that they were actually breaking.

There is no satisfactory theory of the shapes assumed by breaking waves. Stokes, in one of his earlier papers, showed that the irrotational form of wave cannot have an angle of less than 120° at the crest (the corresponding limit for the trochoidal wave, *i.e.* for the cycloid, is 0°), but he considers that the wave will break before the 120° limit is reached.

In the problem presented by breaking waves—as, indeed, in most problems relating to the actual phenomena exhibited by fluids in motion—the simple assumptions on which the hydrodynamical theory of text-books rests are insufficient, and experiments are required.

It would be quite possible to try (say at the Froude tank at the National Physical Laboratory) the effect of a steady artificial wind on a length of several hundred feet of water, and to observe and record the form, length, and velocity of the waves throughout the length of the channel. It would probably be found that the waves were started by the instability due to the discontinuous motion at the boundary of two fluids, and that these waves increased in amplitude only until they began to break, but that after the breaking state was reached the wave-length, as well as the amplitude, increased until there was some approach to equality between the velocity of the wind and the wave.

I have worked out the results for various assumptions as to the rate at which the wind can transfer energy to the water, but in the absence of experimental data the conclusions are scarcely worth publication.

A. MALLOCK.

9 Baring Crescent, Exeter, August 10.

The Antarctic Anticyclone.

IN his letter entitled "The Mechanics of the Glacial Anticyclone Illustrated by Experiment" published in NATURE for July 22, Prof. Hobbs remarks: "In all my writings upon the glacial anticyclone I have been at much pains to explain that the domed surface of the ice is essential to the development both of the anticyclone and of the alternating calms and blizzards which record its strophic action." As, however, one goes on to read the letter one finds that Prof. Hobbs's explanation demands another "essential," namely, that the domed surface must be cooler than the air in contact with it. Remove this defect of temperature, and the mechanism ceases to act; reverse it, and the mechanism works in the reverse direction, producing a cyclone instead of an anticyclone.

Assuming that the Antarctic continent has the domed form postulated by Prof. Hobbs, one might be led to accept his conclusions so far as the winter months are concerned, but what about the summer months? During the summer, with its continuous insolation, the surface of the dome must be at a higher temperature than the adjacent air, for there is plenty of evidence that the temperature of a snow surface is very susceptible to solar radiation. The mean amplitude of the daily variation of air-temperature over the Barrier during November, December, and January was found by Scott's Expedition to be 11·5° F., while between November 17–22, 1911, the average amplitude was 20° F., and this with the sun oscillating only between 10° and 35° above the horizon! If Prof. Hobbs's theory were correct the Antarctic would have a pronounced monsoon climate, while we know from observations that anticyclonic conditions last throughout the year.

G. C. SIMPSON.

London.

Trichodynamics.

THE present writer has had interesting associations since 1915 in various ways with projects for industrial research in the cotton industry and with its actual conduct. In all these the need for a word which would define and describe the field of research peculiar to the textile industries has been intermittently obvious, especially with respect to the processes of spinning and weaving.

In consequence of this I proposed, in the course of the discussion on industrial research at the tenth International Conference held in Zurich in June last, that the word "trichodynamics" should be adopted in order to effect this generalisation, together with the related term "trichostatics." The analogy with aerodynamics is obvious, and hence also my justification for suggesting the word. The word itself is open to question, since, if used in the literal sense, it includes only the hair textiles, *e.g.* wool and cotton, but the significance intended is akin to that of the word "capillary," which now conveys a definite meaning independently of actual hairs.

The chemical and colloidal constitution of textile raw materials, their biology, and the engineering aspects of their utilisation are fields of study not strictly peculiar to the textile industry. On the other hand, the movements and mutual contacts of attenuated filaments and the changes which take place in their arrangement as they pass from the tangle of the raw material to their orderly sequence in yarn or cloth, which the proposed names would cover, form a well-defined field of a peculiar kind which awaits physical investigation.

W. LAWRENCE BALLS.

Edale, Derbyshire, August 11.

Helium: Its Production and Uses.[1]

By PROF. J. C. MCLENNAN, F.R.S.

II.

Miscellaneous Investigations.

IN the course of the investigation on the development of a machine for extracting helium from natural gas, supplies of helium of varying degrees of purity became available. These were highly purified, and used for the investigation of certain collateral problems which demanded solution. Among the results obtained, it was found that for aeronautical purposes hydrogen could be mixed with helium to the extent of 15 per cent. without the mixture becoming inflammable or explosive in air. Mixtures containing even as much as 20 per cent. of hydrogen could be burnt or exploded only when treated in an exceptional manner. The permeability of rubbered balloon fabrics for helium was shown to be about 0·71 of its value for hydrogen. For skin-lined fabrics, the permeability to hydrogen and helium was about the same. Thin soap films were found to be about one hundred times more permeable to hydrogen and helium than rubbered balloon fabrics, but untreated cotton fabrics when wetted with distilled water were but feebly permeable to these gases. It was found that rapid estimations of the amount of helium in a gas mixture could be made with a pivoted silica balance, a Shakspear katharometer, or a Jamin interferometer.

The latent heats of methane and ethane have been determined, as has also the composition of the vapour and liquid phases of the system methane–nitrogen. It has also been shown that helium containing as much as 20 per cent. of air, oxygen, or nitrogen can be highly purified in large quantities by simply passing it at slightly above atmospheric pressure through a few tubes of coconut charcoal kept at the temperature of liquid air. In the spectroscopy of the ultra-violet helium has been found to be exceptionally useful. Arcs in helium between tungsten terminals can be easily established and maintained. In a particular investigation with a vacuum grating spectrograph, it was found that by the use of arcs in helium under 30 cm. pressure illumination could be maintained continuously for hours, and with such arcs spectra could easily be obtained extending to below 1000 Å.U.

Although it is known that free electrons can exist in highly purified helium to an amount easily measurable, it was found that pure helium under a pressure of more than 80 atmospheres did not exhibit anything in the nature of metallic conduction. Moreover, the mobilities of both positive and negative ions formed by α-rays in helium under this high pressure were found to have about one-third the value expected on the basis of an inverse pressure law.

[1] From a lecture delivered before the Chemical Society on June 17. Continued from p. 751.

The Uses of Helium.

The investigation into the problem of producing helium in large quantities was originally undertaken with a view to the utilisation of the gas in aeronautical warfare. The investigation has shown that it can be produced at a cost which is not excessive, but it has also been shown that from the sources in the Empire which are known and have been examined the supply of helium cannot be greater than about 12,000,000 cubic feet per year. This quantity clearly would be sufficient to keep only a very few of our airships of the larger type in commission, even if the gas were diluted to the extent of 15 per cent. with hydrogen. This amount would, however, suffice to keep a number of the smaller aircraft supplied. Moreover, it might be used to fill fireproof compartments adjacent to the engines if it were ever decided to install these within the envelopes of our larger airships.

Since it has been demonstrated that helium can be produced in quantity, one is led naturally to consider in what directions one can hope to use the gas other than that originally intended. In industry it may be used as a filling for thermionic amplifying valves of the ionisation type. It may also be used for filling tungsten incandescent filament lamps, especially for signalling purposes where rapid dimming is an essential, and for producing gas arc lamps in which tungsten terminals are used, as in the "Pointolite" type. Both these varieties of lamp possess the defect, however, of soon becoming dull owing to the ease with which incandescent tungsten volatilises in helium and deposits on the surface of the enclosing glass bulbs. As regards illumination, helium arc lamps possess an advantage over mercury arc lamps in that the radiation emitted has strong intensities in the red and yellow portions of the spectrum.

It has been shown by Nutting (*Electrician*, March, 1912) that Geissler tubes filled with helium are eminently suitable, under certain conditions, for light standards in spectrophotometry, but the amount of the gas which could be used in this way is very small.

In spectroscopy, especially for investigations in the ultra-violet region, helium is invaluable. Doubtless its use in this field will be rapidly extended. The use of the gas in physical laboratories generally, and especially where certain investigations on the properties of matter are carried out, will also be greatly increased.

It has recently been proposed to use helium in place of oil for surrounding the switches and circuit-breakers of high-tension electric transmission lines. If the gas should prove suitable for this purpose, large quantities could be utilised, but it has yet to be demonstrated (and it is not clear

that it can be) that in this field helium possesses any advantage over the oils now used.

It has been suggested by Elihu Thomson and others that if divers were supplied with a mixture of oxygen and helium, the rate of expulsion of carbon dioxide from the lungs might be increased, and the period of submergence as a consequence be considerably lengthened.

It is probable, however, that in the field of low-temperature research helium will immediately find its widest application. For this work helium is unique in that, when liquefied and possibly solidified, it enables one to reach the lowest temperatures attainable. Every effort should be exerted towards the exploitation of its use in this direction.

One point that is important and should not be overlooked is that the supplies of natural gas from which helium can be extracted are being rapidly used up. When our natural gas fields are depleted it would appear that our main source of supply of helium will have disappeared. Careful consideration should, therefore, be given to the problem of producing helium in large quantities while it is still available, and of storing it up for future use. As already stated, it may be that in the future it will be of paramount importance to have even a moderate supply of the gas available.

A Cryogenic Laboratory.

To chemists and physicists especially, the discovery that helium can be produced in quantity at a moderate cost opens up a vista in the realm of low-temperature research of surpassing interest. By means of liquid oxygen, the properties of substances can be studied down to a temperature of $-182.5°$ C. Liquid nitrogen provides us with a temperature of $-193.5°$ C., and hydrogen, which was originally liquefied in 1898 by Sir James Dewar, enables us to reach $-252.8°$ C. It is but a few years since Onnes, after prolonged effort, secured sufficient helium to enable him to liquefy this gas, too. In a brilliantly conceived research he succeeded in accomplishing this feat in 1908, and in doing it reached a temperature within approximately 1° or 2° C. of the absolute zero.

The amount of liquid helium which Onnes obtained in his investigation was small, but it sufficed to enable him to show that a number of the elements possessed a remarkable "super-conductivity" at this low temperature. Mercury in particular, at the temperature of liquid helium, possessed an electrical conductivity ten million times greater than at ordinary room temperature, and currents started by induction in a coil of lead wire at the temperature of liquid helium maintained their intensity for more than an hour with but little diminution in magnitude.

The results obtained by Onnes, although limited in number, are of great importance, for they show that if liquid helium were rendered available in quantity, fundamental information of the greatest value on such problems as those connected with electrical and thermal conduction, with specific and atomic heats, with magnetism and the magnetic properties of substances, with phosphorescence, with the origin of radiation, and with atomic structure, could be obtained.

In spectroscopy supplies of liquid helium would enable us to extend our knowledge of the fine structure of spectral lines, and thereby enable us to obtain clearer ideas regarding the electronic orbits existing in the atoms of the simpler elements. This would lead naturally to clearer views on the subject of atomic structure generally.

In other fields, too, important information could be obtained by the use of temperatures between that of liquid hydrogen and that of liquid helium. What of radio-activity? Would this property be lost by uranium, thorium, radium, and other similar elements at temperatures attainable with liquid helium? Would all chemical action cease at these temperatures? Would photo-chemical action disappear completely? Would photo-electric action cease or be maintained at such low temperatures?

In the fields of biological and botanical research, information on problems pressing for solution could be gained also. For example, would all life in spores and bacteria be extinguished by subjecting them to temperatures in the neighbourhood of absolute zero?

The list of problems rendered capable of attack by the use of liquid helium might be easily extended; but those cited already will serve to show that the field is large, and that it is well worth while for us to make a special effort to secure adequate financial support for the equipment and maintenance of a cryogenic laboratory within the Empire.

It is probably beyond the ordinary resources of any university to equip and maintain such a laboratory; but the project is one which merits national, and probably Imperial, support. It should appeal to private beneficence as well, for it is a project deserving strong and sympathetic help.

A properly equipped cryogenic laboratory should include:

(1) A liquid-air plant of large capacity.
(2) A liquid-hydrogen plant of moderate capacity.
(3) A liquid-helium plant of small capacity.
(4) Machine tools, cylinders, glass apparatus, measuring instruments, etc.

Such an equipment would probably cost more than 10,000*l.*

For building purposes, probably an additional 10,000*l.* or 15,000*l.* would be required.

The staff should include one or two skilled glass-blowers, two or three mechanics and instrument-makers, and two or three helpers for running the machinery. To provide this staff and meet charges for light, heat, and power, probably 3000*l.* a year at least would be needed.

For an administrative and technical staff, probably 2500*l.* would be necessary.

In addition to the above, special provision would have to be made to secure an adequate supply of helium. If industrial uses can be found for helium and a works were established in

Alberta for the production of helium on a large scale, the problem of supply would be solved, for the amount of the gas which would be required for low-temperature research would probably not be more than 20,000 or 30,000 cubic feet a year. In default of a production-works on a large scale being established, it would be necessary to install a small plant at Calgary for the specific purpose of supplying the cryogenic laboratory with helium. This could easily be done at the present time, as the experimental plant is still *in situ*. It would require from 3000*l.* to 4000*l.* to make the changes in the plant which experience has shown are necessary, and to provide the additional auxiliary machinery, tools, etc., required.

If this plant were run for three or four months each year, an adequate supply of helium could be obtained. The expense of running the plant under these conditions would be high, and it would probably be found that it would require from 2000*l.* to 3000*l.* to operate it for a period of three or four months each year. This amount would, of course, have to cover charges for salary of staff, compensation to the owners of the natural gas, light, power, miscellaneous supplies, freight charges on cylinders, etc.

From the above it will be seen that a scheme such as that outlined would require in the aggregate a capital expenditure of about 30,000*l.* for buildings and plant, and the interest on an endowment of about 125,000*l.* for operating and maintaining the cryogenic laboratory, together with the supply station.

If a cryogenic laboratory, with its auxiliary supply station, were established along the lines indicated, it would probably be found to be more economical to run the supply station continuously for a number of years, and to store for future use the helium accumulated. In this connection it should be stated that the experimental plant as it exists would probably not produce more than 100,000 cubic feet of helium per year. The plant could, however, be easily manifolded, and the Governments of Great Britain and Canada might, from the point of view of national safety, legitimately be asked to assume responsibility for operating it.

Much of our knowledge acquired in the field of low-temperature research we owe to the brilliant work of such distinguished men as Andrews, Davy, Faraday, and Dewar. The discovery of the rare gases, helium, neon, argon, krypton, and xenon, we owe to Lockyer, Rayleigh, Ramsay, and Dewar. How could we more fittingly perpetuate the work of these great men than by establishing on a permanent basis a cryogenic laboratory for the purpose of making still further progress in the field of low-temperature research—a field in which British men of science have made such brilliant and notable advances?

The Cardiff Meeting of the British Association.

IT is twenty-nine years since the Association met in Cardiff. It is safe to say that any members who may have been present on that occasion will not now be able to recognise the city, for there can scarcely be any other town in the country which has not merely grown, but also altered, so much in that period. In 1891 there was on the north side of what is now one of the main streets a large tract of finely timbered ground called Cathays Park, adjacent to Cardiff Castle and its park, and also the property of the Marquess of Bute. In Cathays Park now stand a number of large and handsome public buildings, including the City Hall, Law Courts, University College, Technical College, and the National Museum of Wales. These are the buildings in which the meetings of the Association will take place, and not one of them was in existence at the time of the former meeting.

As usual, it is difficult to estimate the probable success of the meeting from the point of view of numbers, but locally every effort is being made to ensure it, and a good average meeting is expected. It is certain that the Association can never have been better provided in the matter of meeting rooms and lecture halls. The local arrangements are now almost complete. The housing shortage, particularly serious in Cardiff, and the fact that this is the holiday season have made the task of the rooms and hospitality committees rather trying, but it has been accomplished, and ample accommodation will be available.

The reception room, general offices, post office, and luncheon and tea room are situated in the City Hall; Sections A, F, H, and L meet in the University College; Section G has the use of the South Wales Institute of Engineers close by; and all the other sections are accommodated in the Technical College. In the Technical College also there is an assembly hall for special meetings. The inaugural general meeting, evening discourses, and citizens' lectures take place in the Park Hall, which is near one corner of Cathays Park.

Regarding the programmes of the individual sections, little can be added to the account of them published in NATURE of July 15. The journal of sectional and other proceedings will be ready on the first day of the meeting, but has lost its right to the name, for it will not be published daily as hitherto. Members should therefore retain their copies throughout the meeting. Any alterations in the sectional programmes will be shown from day to day on the notice board in the reception room.

The inaugural general meeting will take place on Tuesday, August 24, in the Park Hall, at 8 p.m., when the president, Prof. W. A. Herdman, will deliver his address. On Wednesday there will be a reception by the Lord Mayor of

Cardiff at the University College at 8 p.m. The evening discourses by Sir R. T. Glazebrook and Sir Daniel Hall will be delivered in the Park Hall at 8 p.m. on Thursday and Friday respectively. The conference of delegates of corresponding societies will be held at 2 p.m. on Wednesday and on Friday in the assembly hall of the Technical College.

Three citizens' lectures will be delivered in the Park Hall at 8 p.m. on Monday, Wednesday, and Saturday, the lecturers being respectively Prof. J. Lloyd Williams ("Light and Life"), Prof. A. W. Kirkaldy ("Present Industrial Conditions"), and Dr. Vaughan Cornish ("The Geographical Position of the British Empire"). Members of the Association as such are not admitted to these lectures. The distribution of tickets, which are free, is in the hands of the Workers' Educational Association, and they may be obtained at the reception office during the meeting.

The programme of excursions is a varied one. The geologists are visiting Cefn On and Caerphilly on Tuesday, Penylan on Wednesday, the Barry Coast on Thursday, and Lavernock on Friday. Section E (Geography) will explore the Vale of Glamorgan on Wednesday, and the Taff and Rhondda Valleys on Thursday. The engineers will be shown over the Bute Docks on Tuesday, the Melingriffith Tinplate Works on Wednesday, the Dowlais Steelworks on Thursday, and the Great Western Colliery on Friday. Section H (Anthropology) will investigate the Roman remains at Caerwent (between Newport and Chepstow) on Wednesday. A botanical expedition to Wenvoe takes place on Thursday. The Section of Education will inspect the summer school at Barry on Friday. One or two demonstrations have also been arranged. On Wednesday Section I will be shown the new physiological laboratories of the University College, where a new electrokymograph will be demonstrated. On Thursday afternoon members of the Association, particularly those of Sections B, A, and I, are invited to the chemical laboratories of the Cardiff City Mental Hospital, where demonstrations will be given of some new chemical and physiological methods, and also of a modern high-powered X-ray installation equipped with auto-transformer and Coolidge tube. All these sectional excursions and demonstrations take place in the afternoons.

On Saturday, August 28, two general excursions of the Association will be made. One party will drive through the Wye Valley, taking lunch at Tintern and calling at Llanover, near Abergavenny, at the invitation of Lord Treowen, to take tea on the return journey. The other party will cross the Bristol Channel and visit the famous Cheddar caves, Wells Cathedral, and Glastonbury Abbey. The numbers in these excursions (and also in many of the sectional expeditions already mentioned) are limited. Members are requested to signify their intention of taking part in any of them as soon as possible after the beginning of the meeting. By so doing they will not only ensure their own participation, but also lighten the work of those responsible for organising the excursions, for in the present local conditions the difficulties of arranging transport are considerable.

Obituary.

Sir Norman Lockyer, K.C.B., F.R.S.

THE death of Sir Norman Lockyer on Monday last deprives the world of a great astronomer, and the nation of a force which it can ill afford to lose. Though it had been known for several months that Sir Norman was in a feeble state of health, his many friends cherished the hope that the vigour which was characteristic of him would revive, and that the devoted attention of his wife and daughter would preserve him to us for a few more years; but this was not to be. The alert mind and acute understanding which influenced so many men and advanced so much scientific work over a period of sixty years or so are now at rest, yet there remains to us a recollection which will not soon be effaced, and there stands in the archives of science a record of his achievement which will command admiration so long as the pursuit of knowledge is regarded as worthy human endeavour.

In the jubilee issue of NATURE in November last Dr. Deslandres, Sir Archibald Geikie, Sir Ray Lankester, and other distinguished men of science paid tribute to the work and influence of the founder of this journal, the volumes of which form an enduring monument to his memory.

Sir Norman was not only a pioneer worker in the fields of science, but also an advocate of the claims of science to recognition in modern polity, and this rare combination was used to further scientific interests as well as to secure the progress of knowledge. He was the embodiment of mental activity, and never relinquished a task to which he had put his hand. Until a short time ago he was as eager to learn of developments and discoveries in astronomical work, and as ready to suggest new lines of research, as a man in the prime of life, and it is difficult to realise that this fund of energy is now no longer available to those of us who derived benefit from it. When Goethe wrote: "The quickening power of science only he can know from whose soul it gushes free," he must have had in mind a researcher of the type of him whose loss we now mourn.

Sir Norman Lockyer was born at Rugby on May 17, 1836. He was educated at various private schools, and in 1857 received an appointment at the War Office. His work there was so much appreciated that in 1865 he was entrusted with the editorship of the Army Regulations. In 1870 he was appointed secretary of the Duke of Devonshire's Royal Commission on scientific

instruction and the advancement of science. The reports of this Commission are most valuable records of the position and needs of science, and if the recommendations had been put into force this country could easily have been in advance of all others as regards scientific development. When the work of the Commission was completed in 1875 Sir Norman was transferred to the Science and Art Department. He afterwards became professor of astronomical physics in the Royal College of Science, and was director of the Solar Physics Observatory at South Kensington from 1885 to 1913. He was elected a fellow of the Royal Society in 1869, was Rede lecturer to the University of Cambridge in 1871, and Bakerian lecturer to the Royal Society in 1874, in which year he received the Rumford medal of the society. In 1875 the Paris Academy of Sciences elected him a corresponding member in the section of astronomy. He was a corresponding member of numerous national scientific societies, and honorary member of many others. He received honorary degrees from the Universities of Oxford, Cambridge, Glasgow, Edinburgh, and Aberdeen, and the Order of Knight Commander of the Bath was conferred upon him by the King in 1897.

Sir Norman Lockyer's early spectroscopic work was devoted to the sun. His first observations were directed to a scrutiny of the spectrum of sunspots as compared with that of the general surface. In the course of the paper in which these observations were described, read before the Royal Society on November 15, 1866, he remarked:—"May not the spectroscope afford us evidence of the existence of the 'red flames' which total eclipses have revealed to us in the sun's atmosphere, although they escape all other modes of examination at other times?" The spectroscope he then employed proved to be of insufficient dispersive power for his researches, but by the aid of the Government Grant Committee of the Royal Society an instrument of greater power, though not quite complete, was obtained on October 16, 1868. Four days later his efforts were crowned by the detection of a solar prominence by means of the bright lines exhibited in its spectrum. An account of this discovery was immediately communicated to the Royal Society and to the Paris Academy of Sciences. Meanwhile had occurred the total solar eclipse of August 18, and Dr. Janssen, who had observed with eminent success the spectrum of the prominences during the eclipse, came to the conclusion that the same mode of observation might enable one to detect them at any time, and he saw them in this manner the next day. The first account of the discovery, which was sent by post, reached the Paris Academy a few days after the communication of Sir Norman Lockyer's observation of October 20, and, as was described in NATURE of May 20 last, a medal was struck in honour of the joint discovery.

This notable application of the spectroscope revealed the prominences as local disturbances in the continuous luminous layer which Sir Norman Lockyer called the chromosphere, and from the field of research opened by his discovery rich harvests have since been reaped. The gas, named by him helium, commonly occurring in solar prominences, was not isolated on the earth until twenty-seven years later, when Sir William Ramsay extracted it from the mineral clèveite. Now, as Prof. McLennan has described in these columns, it is possible to obtain millions of cubic feet of helium per day from natural gas in Alberta, and there is every reason to believe that this supply will become of immense scientific and industrial value.

It is beyond the bounds of this general record of Sir Norman Lockyer's scientific services to venture into the field of astronomical physics which he made particularly his own. An appreciative account of that work will be contributed to a later issue by a spectroscopist familiar with its special significance and value. Here we need only remark that Sir Norman's meteoritic hypothesis of celestial evolution is chiefly responsible for the change of view which has taken place as to the nature of nebulæ and the existence of stars of increasing as well as of decreasing temperatures. Dark nebulæ—sheets or streams of non-luminous cosmic dust—are no longer considered hypothetical, but are as real as dark stars, and the incipient luminosity of nebulæ in general represents the visible portion only of vastly more extensive congeries of invisible cosmic matter. Some of the most noteworthy discoveries of astronomical science in recent years are, indeed, those which suggest or demonstrate that space may include as much dark matter as bright, and they largely owe their origin to Sir Norman Lockyer's meteoritic hypothesis and the classification of stellar types based upon it.

In his work and conclusions upon the subject of dissociation, Sir Norman Lockyer was likewise much in advance of his times. Fifty years ago he was convinced by his spectroscopic observations that the view that each chemical element had only one line spectrum was erroneous, and that the various terrestrial and solar phenomena were produced by a series of simplifications brought about by each higher temperature employed. In his studies of dissociation he was really collecting facts concerning the evolution of the chemical elements, and he pointed out especially that the first steps in this evolution were probably best determined by observations of stellar spectra.

Sir Norman Lockyer was the chief of eight British Government solar eclipse expeditions, and organised the programmes of several others while director of the Solar Physics Observatory. His use of the slitless spectroscope during the eclipses from 1871 onwards provided a wealth of information for study. From the photographs obtained during the total solar eclipse of 1893 the wave-lengths of many chromospheric and coronal lines were determined, and a very complete series of pictures and spectra of the corona and chromosphere was obtained during the

eclipse of 1898, the true wave-length of the chief corona line being then determined as 5303·7. Further knowledge was secured from the eclipses of 1898, 1900, and 1905, and it was all brought into relationship with the laboratory work and discussions of stellar types carried on at the Solar Physics Observatory.

When the first Solar Physics Committee was appointed in 1879, reference was made to the desirability of an inquiry into the possible effect of solar conditions on meteorological phenomena, but it was not until 1898 that Sir Norman Lockyer undertook, with his son, Major W. J. S. Lockyer, a definite and searching inquiry into the most trustworthy meteorological records, with the view of discovering indications of solar influence on weather factors. It was established that the oscillations of annual pressure in South America are closely related to those of the Indian Ocean, but inverse in character, high pressure years in India being represented by low pressure years in Cordoba. This "see-saw" phenomenon was found to hold good for numerous other districts, and its importance for long-period forecasting is now being recognised. Drs. Helland-Hansen and Nansen refer particularly to the work of Sir Norman and Major Lockyer upon this subject in their valuable memoir noticed in NATURE of August 5, p. 715.

A report on the work of the Solar Physics Observatory during the period 1889–1909 was issued by Sir Norman Lockyer when the Solar Physics Committee was dissolved and the observatory transferred to Cambridge. This abrupt break in his life's work was acutely felt by Sir Norman, and he never really recovered from its effects, though he was as keen as ever upon progress in astrophysics. What he desired particularly was that the observatory should be transferred to a site which would permit increased opportunity for observation, and when, to his great disappointment, the institution to which he had devoted so many active years was summarily reorganised without consideration for his interests in it, and placed in a position little better than that which it had long occupied under his directorship, his hope for the development of astrophysical researches started at the observatory received a sudden and pathetic check.

Obstacles were, however, always used by Sir Norman Lockyer as opportunities. When the Solar Physics Observatory was taken from South Kensington to Cambridge in 1913, and his official connection with the observatory ceased, he devoted himself to erecting a new observatory at Salcombe Regis, Sidmouth, where he spent his declining years. Later, the Hill Observatory Corporation was formed to promote the development of this observatory and to carry on its work permanently. Sir Norman and Lady Lockyer gave the site of seven and a half acres upon which stand the present buildings, and there is ample room for extension, while the position of the observatory is as fine as could possibly be desired. Thanks chiefly to Sir Norman's gifts of instruments and to the generosity of Lt.-Col. Frank McClean, Mr. Robert Mond, and others, the observatory is already one of the best equipped in the country, and it could become one of the best in the world if wealthy benefactors here were as much interested in the promotion of astronomical science as they are in the United States, where the most notable work is now being done in astrophysics. No memorial to Sir Norman Lockyer could have a more appropriate object than that of providing means to increase the staff and develop the work of the Hill Observatory.

Sir Norman Lockyer's archæological observations are not so well known as they should be, for most of them belong to the first rank. In continuation of his work on the astronomical uses of Egyptian temples, he turned his attention to some of the stone circles and other stone monuments in this country, and he was able to establish the conclusion that such monuments were built to observe and mark the rising and setting of the sun and other heavenly bodies at different times of the year. The date of construction of Stonehenge was thus found to be between about 1900 and 1500 B.C., and it appeared that a thousand years before circles were built in Cornwall, commencing about 2400 B.C., avenues were erected in other parts of Britain.

When president of the British Association in 1903–4, Sir Norman Lockyer delivered at the Southport meeting a notable address on "The Influence of Brain-power on History." This address attracted wide attention, but the nation was not then ready to learn the lesson taught by it, and it has taken the greatest war of all time to awaken national consciousness to its significance. A strong plea was made to prepare by intellectual effort for the struggles of peace and of war, and it was added:—"Such an effort seems to me to be the first thing any national or Imperial scientific organisation should endeavour to bring about." Sir Norman Lockyer hoped that the British Association would expand one of its existing functions and become the active missionary body adumbrated in his address; but his appeal did not meet with the active support he expected from the council, most of the members of which were more interested in scientific work itself than in national aspects of it. With characteristic energy, however, Sir Norman set himself the task of establishing an organisation which would bring home to all classes of the community the necessity of making the scientific spirit a national characteristic to inspire progress and determine policy in affairs of all kinds, and as a result the British Science Guild was founded in 1905.

Throughout his career Sir Norman Lockyer's public activities made contact with national life at many points, and the British Science Guild is an institutional representation of them which remains to attain the objects at which he consistently aimed. The purpose of the Guild is to stimulate not so much the acquisition of know-

instruction and the advancement of science. The reports of this Commission are most valuable records of the position and needs of science, and if the recommendations had been put into force this country could easily have been in advance of all others as regards scientific development. When the work of the Commission was completed in 1875 Sir Norman was transferred to the Science and Art Department. He afterwards became professor of astronomical physics in the Royal College of Science, and was director of the Solar Physics Observatory at South Kensington from 1885 to 1913. He was elected a fellow of the Royal Society in 1869, was Rede lecturer to the University of Cambridge in 1871, and Bakerian lecturer to the Royal Society in 1874, in which year he received the Rumford medal of the society. In 1875 the Paris Academy of Sciences elected him a corresponding member in the section of astronomy. He was a corresponding member of numerous national scientific societies, and honorary member of many others. He received honorary degrees from the Universities of Oxford, Cambridge, Glasgow, Edinburgh, and Aberdeen, and the Order of Knight Commander of the Bath was conferred upon him by the King in 1897.

Sir Norman Lockyer's early spectroscopic work was devoted to the sun. His first observations were directed to a scrutiny of the spectrum of sunspots as compared with that of the general surface. In the course of the paper in which these observations were described, read before the Royal Society on November 15, 1866, he remarked:—"May not the spectroscope afford us evidence of the existence of the 'red flames' which total eclipses have revealed to us in the sun's atmosphere, although they escape all other modes of examination at other times?" The spectroscope he then employed proved to be of insufficient dispersive power for his researches, but by the aid of the Government Grant Committee of the Royal Society an instrument of greater power, though not quite complete, was obtained on October 16, 1868. Four days later his efforts were crowned by the detection of a solar prominence by means of the bright lines exhibited in its spectrum. Frank McClean, Mr. Robert Mond, and others, the observatory is already one of the best equipped in the country, and it could become one of the best in the world if wealthy benefactors here were as much interested in the promotion of astronomical science as they are in the United States, where the most notable work is now being done in astrophysics. No memorial to Sir [illegible] more appropriate

[illegible]man Lockyer's archaeological [illegible]tions are not so well known as they should be, for most of them belong to the first rank. In continuation of his work on the astronomical uses of Egyptian temples, he turned his attention to some of the stone circles and other stone monuments in this country, and he was able to establish the conclusion that such monuments were built to observe and mark the rising and setting of the sun and other heavenly bodies at different times of the year. The date of construction of Stonehenge was thus found to be between about 1900 and 1500 B.C., and it appeared that a thousand years before circles were built in Cornwall, commencing about 2400 B.C., avenues were erected in other parts of Britain.

When president of the British Association in 1903–4, Sir Norman Lockyer delivered at the Southport meeting a notable address on "The Influence of Brain-power on History." This address attracted wide attention, but the nation was not then ready to learn the lesson taught by it, and it has taken the greatest war of all time to awaken national consciousness to its significance. A strong plea was made to prepare by intellectual effort for the struggles of peace and of war, and it was added:—"Such an effort seems to me to be the first thing any national or Imperial scientific organisation should endeavour to bring about." Sir Norman Lockyer hoped that the British Association would expand one of its existing functions and become the active missionary body adumbrated in his address; but his appeal did not meet with the active support he expected from the council, most of the members of which were more interested in scientific work itself than in national aspects of it. With characteristic energy, however, Sir Norman set himself the task of establishing an organisation which would bring home to all classes of the community the necessity of making the scientific spirit a national characteristic to inspire progress and determine policy in affairs of all kinds, and as a result the British Science Guild was founded in 1905.

Throughout his career Sir Norman Lockyer's public activities made contact with national life at many points, and the British Science Guild is an institutional representation of them which remains to attain the objects at which he consistently aimed. The purpose of the Guild is to stimulate not so much the acquisition of know-

ledge as the appreciation of its value, and the advantage of applying the methods of scientific inquiry in affairs of every kind. Such methods are not less applicable to the problems which confront the statesman, the administrator, the merchant, the manufacturer, the soldier, and the schoolmaster than to those of the scientific worker. These were the convictions of Sir Norman Lockyer, and he had the satisfaction in recent years of hearing them proclaimed from the housetops, while the Guild itself stands as a monument of their power and his prescience.

In 1904 a large and influential deputation urged upon Mr. Balfour, then Prime Minister, the need for further assistance to university education and research, and in announcing that the grant would at once be doubled, as well as redoubled in the following year, Mr. Balfour stated that the increase, which represented a capital sum of 3,000,000*l.* at 2½ per cent., was given as the result of the appeal made in 1903 by Sir Norman Lockyer in his presidential address to the British Association at Southport. This represents one result only of his ceaseless activity on behalf of science and higher education; the pages of NATURE throughout its existence afford ample testimony of the use of the same zeal for progress.

"There must," he once said, "be only one kind of education—the best—and that is to be given to everybody." He expected the best work from everybody associated with him, and would not tolerate any lower standard for either individual or national aims. His fingers have now loosed their grasp upon the torch of science which he held aloft for so many years, but the light still burns on the bank of the dark river he has crossed; and in admiration, hope, and reverence it will be borne onwards by workers whom he inspired. His body will be laid to rest on Saturday morning at Salcombe Regis Church, Sidmouth, but his spirit will remain in the observatory on the hill-top near-by to stimulate others to reach out and touch the sky.

Sir Edward Brabrook writes:—

Among the many who have been honoured by the friendship of Sir Norman Lockyer and are in sorrow at his death, I count myself, as having had opportunities of being associated with him in more than one capacity. I was one of those members of the Civil Service whom he invited to join with him in a welcome to Mowatt, of the Treasury, on the occasion of his election as a member of the Athenæum. In the year when Sir Norman presided over the British Association, I was one of the sectional presidents, and was nominated by him as a member of the council. I warmly sympathised with the wishes he then entertained for the extension of the functions of the association, and when these were seen to be not realisable in the form in which he desired them, I accepted his invitation to join in the formation of the British Science Guild. Others will be better able than I to tell the story of his labours for that institution, and of the success that has attended them; but I may say a few words on another aspect of his untiring intellectual work, viz. his contributions to archæology. In this respect he was an example of the interdependence that exists between the sciences, for it was the pursuit of his favourite science of astronomy that gave the direction to his studies of ancient civilisation. In the temples of Egypt and in the stone circles of our own country he found evidence of the astronomical knowledge and purpose with which they were erected, and his own profound acquaintance with the problems they presented to him from that point of view led him to conclusions which, as in the case of fixing the date of Stonehenge, were closely verified by the evidence afterwards derived from excavations on the spot.

AGRICULTURAL chemistry has lost a distinguished exponent by the death of PROF. EDWARD KINCH on August 6 at the age of seventy-one. Prof. Kinch was educated at the Grammar School, Henley-on-Thames, and the Royal College of Chemistry, and successively occupied the following positions:—Chief assistant to the professor of chemistry (the late Sir Arthur Church) at the Royal Agricultural College, Cirencester, 1869–73; on chemical staff of Royal School of Mines, 1873–75; superintendent of minerals, India Museum, 1875–76; professor of chemistry, Imperial College of Agriculture, Tokyo, 1876–81; professor of chemistry, Cirencester, 1881–1915, when the Royal Agricultural College closed on account of the war. He published many technical papers on agricultural chemistry, in which he was a leading authority, always distinguished by the soundness of his judgment. As a teacher Prof. Kinch did much for his subject both in this country and in Japan, and he will be remembered with respect and affection by many generations of students and numerous former colleagues. His life was saddened by the premature death of his young wife (a daughter of the late Rev. Geo. Huntington), whom he married in 1889, and after this he led a somewhat retired life. Those privileged to be his intimate friends will not easily forget his many sterling qualities and quiet sense of humour.

J. R. A.-D.

WE regret to note that the death of MR. JOHN KIRKALDY is announced in *Engineering* for August 13. Mr. Kirkaldy was born in 1853, and was head of the well-known London firm of John Kirkaldy, Ltd. Quite early in life he took over the management of his father's business, and under his direction the firm played an important part in introducing fresh-water distilling apparatus for use on board ship. Plant of this kind was also designed for use in the Ashanti campaign, and in 1883 and 1885 in connection with the Egyptian campaigns. Mr. Kirkaldy was a member of the Institution of Civil Engineers, and also of the Institution of Mechanical Engineers.

Notes.

ARCHÆOLOGISTS will fully appreciate the announcement that one of the first official acts of the new High Commissioner of Palestine has been the establishment of a Department of Antiquities. An International Board will advise the director on technical matters. Provision is made for an inspector, for a museum, and for the custody of the historical monuments. The museum starts with more than 100 cases of antiquities collected by the Palestine Exploration Fund and other bodies before the war. On August 9 the new British School of Archæology was formally opened at Jerusalem by Sir Herbert Samuel.

AT the council meeting of the National Association of Industrial Chemists, held at Sheffield on August 7, the hon. secretary reported that a number of firms had given a definite undertaking to consult the officials of the association in all matters relating to chemists, their appointment, salaries, and conditions of employment. On the whole, the salaries paid to members of the association were fairly satisfactory; in this connection a report had been issued giving a schedule of minimum salaries, and this would be circulated shortly. The hon. secretary took a gloomy view of the future before industrial chemists. He stated that the number of unemployed was increasing rapidly, and there was every indication of a coming great slump in the engineering and allied industries in which their members were employed. It was more than ever imperative for industrial chemists to unite to preserve their interests. Mr. A. B. Searle (Sheffield) was unanimously elected president for the coming year, and Mr. J. W. Merchant appointed secretary. The proposal to appoint an organising secretary for propaganda work was also carried.

A MEMORIAL has been presented to the German National Assembly urging the formation of an Imperial Chemicotechnical Test Laboratory, which it is recommended should be formed from the Military Test Bureau which existed during the war. According to a report in the *Zeits. des Vereines deutscher Ingenieure* for May 29, it is suggested that the functions of the new laboratory should be, *inter alia*, the execution of scientific and technical investigations relative to raw materials, and particularly (1) the production of materials of importance to the public, *e.g.* spirit from wood and acetylene instead of from potatoes, and of fatty acids from the products of coal- or lignite-tar or paraffin, and the utilisation and improvement not only of cellulose as a substitute for cotton, but also of ammonium nitrate obtained synthetically in large quantities as a fertiliser; and (2) the determination of substitutes for chemical and metallurgical products not available in the country or of which there is a shortage, *i.e.* substitutes for paraffin, camphor, and glycerine, for substances used in the preservation of leather and metals, also substitutes for lubricants, rubber, gutta-percha, etc. In addition, the proposed new institute would carry out researches of general interest, *e.g.* on rust-prevention and the corrosion of metals, on the determination of stresses in internal-combustion engines, on the effect of winter cold and upper-air temperatures on implements and raw materials, and on the testing and improvement of aeroplane and airship fabrics. It is also suggested that scientific and technical investigations should be carried out dealing with the prevention of accidents and the protection of workers in a number of important industries.

THE autumn meeting of the Institute of Metals will be held at Barrow-in-Furness on September 15–16, under the presidency of Sir George Goodwin.

WE have received the quarterly report of the Research Defence Society containing an account of the annual general meeting. The Jenner Society has become affiliated to the society, and its hon. secretary, Dr. Drury, has joined the committee. At the close of the meeting Col. McCarrison gave an address on "Vitamines," an abstract of which is published in the report.

Medical Science: Abstracts and Reviews for August (vol. ii., No. 5) contains a review of recent work and articles upon "lethargic encephalitis" (see NATURE, January 1, p. 452), a disease which appeared in this country at the commencement of 1918. Cases have been reported in almost every European country and in Africa, India, the United States, and Canada. Netter points out that descriptions of a similar disease are given by Hippocrates, Aretæus, and Cælius Aurelianus, and the works of Celsus contain a chapter on "lethargic fever." Sydenham in the seventeenth century also gave a description of the same kind of disease under the name of "comatose fever." It appears reasonable to suppose, therefore, that this disease is not new, but has been in abeyance for seventy years or more. No causative organism has yet been discovered.

ON the occasion of the opening of the third laboratory of the Liverpool School of Tropical Medicine on July 24 (see NATURE, July 29, p. 696) the Liverpool University Press issued a volume (103 pp., 37 plates) giving an account of the inception of the School and its history from that time up to the present. In addition to the records of the important contributions of the School to the advance of our knowledge of tropical diseases, the volume records the benefactions which have enabled the School to develop and to perform its functions so successfully. Among recent developments may be mentioned the establishment of research laboratories at Manáos and at Sierra Leone, where continuous investigations into the diseases of these localities can be carried on. We join in the confident hope expressed that the city of Liverpool and those "whom destiny binds in diverse ways to tropical lands" will continue to support the School.

THE Research Defence Society has issued a paper by Major-Gen. Sir David Bruce on the prevention of tetanus during the Great War by the use of antitetanic serum. Sir David Bruce states in his introduction that the object of this paper is to controvert the assertions of the supporters of anti-vivisection in regard to tetanus, and to prove that antitetanic serum

is of the greatest use in preventing the onset of the disease, and if not successful in this, in mitigating the severity of the symptoms and lessening the death-rate. Statistics of the incidence of tetanus among the wounded sent home, about 1,242,000, are given; there were among them 1458 cases of tetanus, a ratio of about 1 per 1000. In September, 1914, 6000 wounded men were landed in England, and 54 men wounded in that month were attacked by tetanus, a ratio of 9 per 1000. In November, 1914, there was a sudden drop to a ratio of 2·3 per 1000, and the ratio never afterwards exceeded about 2·7, and was frequently less. This sudden drop coincides with the systematic inoculation of all the wounded with antitetanic serum. The case-mortality per cent. of those who developed tetanus was 53·5 among those unprotected with antitetanic serum, and 23·0 among those who received a preventive injection of the serum. The use of antitetanic serum also markedly lengthened the incubation period of the disease, and the longer the incubation period, the milder does the disease tend to be. With a long incubation period the disease frequently assumes a localised form in the neighbourhood of the wound, and while in 1914 the percentage of cases of the acute and generalised form was 98·9 and of the local form 1·1, in 1918 the respective figures were 83·5 and 16·5. Sir David Bruce concludes, therefore, that by the preventive use of antitetanic serum (1) the incidence of the disease is lowered ten to twelve times; (2) the incubation period is lengthened four or five times; (3) the disease becomes milder, many of the cases showing only local manifestations; and (4) the death-rate is lowered fourfold.

FOUR specimens of Gephyrea were taken from the stomachs of fish at two widely separated stations by the Canadian Arctic Expedition, 1913–18. These are referred by Mr. R. V. Chamberlin (Report of the Expedition, vol. ix., Part D, 1920) to the widespread northern *Priapulus humanus*. A short account is given of other Canadian Gephyrea, which represent six species—the Priapulus already mentioned and five Sipunculids, one of which is a new species of Phascolosoma. The author appends a useful, but not quite complete, bibliography of the Gephyrea containing the titles of about 430 works.

THE remarkable habits of the sage grouse form the subject of a brief but valuable essay by Mr. Bruce Horsfall in *Zoologica* (vol. ii., No. 10), the organ of the New York Zoological Society. One of the most striking features of the displays described is the use of the wings in thrusting forward the inflated air-pouch, which plays a prominent part in the performance. The author contends that these displays are not "courtship" antics, because no notice was taken of one or two females which "meandered through the throng" while the performance was in full swing. But since the breeding season seems only just to have begun, one feels inclined to doubt the validity of this interpretation. A number of unusually good text-figures and a coloured plate add greatly to the value of this most welcome addition to our knowledge of the ecology of the sage grouse.

THE nesting of the bee-eater in Scotland is an event in the annals of British ornithology which is indeed worthy of record, and we are greatly indebted to Mr. J. Kirke Nash for his carefully kept notes thereon which he publishes in *British Birds* for August. A pair of these birds were first seen on June 3 perched on a wire fence surmounting a sand-bank of the River Esk, near Musselburgh. When discovered they were engaged in catching flies, after the fashion of the flycatcher. On June 7 they were found entering and leaving a hole in the bank, and as the male was seen feeding his mate it was clear that they were nesting. On June 13, however, the female fell a victim to the stupidity of a gardener, who captured it, placed it in a greenhouse, and "fed" it on breadcrumbs. Needless to say, it died within two days, after laying an egg. A few days later the unfortunate survivor was caught and killed by a cat.

DR. B. H. RANSOM contributes to the Proceedings of the United States National Museum (vol. lvii., pp. 527–73, 33 figs., 1920) a synopsis of the Trematode family Heterophyidæ, with descriptions of a new genus and five new species. This family is composed of a number of genera of small Trematodes, usually not more than 2 mm. long, parasitic in the intestine of mammals and birds, usually fish-eaters. Two of these flukes, *Heterophyes heterophyes* and *Metagonimus Yokogawai*, occur in the small intestine of man—the former in Egypt, China, and Japan, and the latter in Formosa, Japan, and Korea. These occur also in the dog and cat, and five other flukes of this family have been recorded from these animals. The author gives a key to the characters of the nine genera which he recognises as valid, and also supplies the necessary keys to the species.

THE first annual report of the Industrial Fatigue Research Board (H.M. Stationery Office) contains an interesting record of work completed or in progress. Of the four reports already issued that of Dr. Vernon dealing with the influence of hours of work and ventilation on output in the tinplate industry is the most extensive, while the report by Mr. Major Greenwood and Miss Hilda Woods upon the incidence of industrial accidents (the statistical theory of this investigation has been further developed in a paper by Messrs. Greenwood and Yule published in the March, 1920, issue of the Journal of the Royal Statistical Society) suggested some important problems which the Board proposes to study further. Mrs. Osborne's paper on the output of female munition workers and Dr. C. S. Myers's analysis of the results obtained in a factory after the introduction of motion study are also of interest. Amongst investigations not yet completed, that on the relation between length of shift and fatigue in the iron and steel industry, entrusted to Dr. H. M. Vernon, is almost ready for publication, and progress has been made with inquiries into special conditions affecting the cotton, boot and shoe, and silk industries. The Board has a large number of tasks in hand, and it is yet too early to decide which are likely to be most remunerative. It is, however, clear that careful thought has been

devoted to the organisation of research, and we have no doubt that the outcome will be of the greatest benefit to both employers and employed.

COPIES of new editions of several pamphlets in the Economic Series published by the Natural History Museum have come to hand. No. 1 on the house-fly (*Musca domestica*) by Major Austen is in its third edition, and has been enlarged and almost entirely rewritten. It deals with the house-fly under normal conditions in the British Isles; those who desire further information, including Army requirements, should consult the larger pamphlet, No. 1A, in the same series. The illustrations are exceedingly clear, and several of these, along with the letterpress, will help to distinguish the commoner house-frequenting flies from the true house-fly, which they closely resemble. *Musca autumnalis* is a case in point; it frequently enters houses, etc., and hibernates therein during the winter, giving rise to the popular belief that the winter habits of *M. domestica* are well known. The latter feature, however, is one concerning which we need much more extensive observation than has been accorded to it in the past. The breeding habits of the house-fly are also dealt with, and simple remedial and preventive measures against this pest are enumerated. No. 3, by Mr. J. Waterston, deals with fleas and their relation to man and domestic animals. It is noteworthy that eleven species have up to the present proved capable of transmitting plague. Five of them are common in Britain, while the plague-flea *par excellence* (*Xenopsylla cheopis*) is occasionally introduced. No. 4, on mosquitoes, is written by a recognised student of the family, Mr. F. W. Edwards. The relation of these insects to disease and the control measures in vogue are clearly explained. No. 6, by Mr. H. Hirst, deals with scorpions, mites, ticks, spiders, and centipedes in so far as they may be injurious to man. Nos. 3 and 6 are reprints, without alterations, of their predecessors, and No. 4 differs from its original edition only in a few small additions to the letterpress.

AN interesting account of the development of the mica industry in Eastern Transvaal during the last ten years is given by Mr. A. L. Hall in Memoir 13 of the Geological Survey of the Union of South Africa (1920). The "books" of mica that are of economic value occur as constituents of coarse-grained pegmatites which cut the older granite of the Pietersburg district. The memoir gives a review of the uses of mica and of the qualities and occasional defects that must be considered from a commercial point of view.

MR. SEITARÔ TSUBOI has published a complete study, structural and petrographical, of the island volcano of Oshima, the largest of the "Seven Islands" group south-west of the Bay of Tokyo (Journ. Coll. of Sci., Imp. Univ. Tokyo, vol. xliii., May 10, 1920). Incidentally, he introduces a method for the determination as nearly as possible of the maximum and minimum refractive indices of minerals represented by minute crystal grains, by using a large number of grains immersed in various liquids above a Nicol. The great crater-ring formed by ancient ejecta is now dominated by the recent central cone of Miharayama, which is still active. The author is not afraid of technical terms, and concisely describes the volcano as consisting of "double homates—a somma and a central one," and as "built up of numerous layers alternately accumulated of rheumatitica and clasmatica of basaltic nature."

MR. H. VALENTINE DAVIS sends us a copy of his "Little Book about Snowdon," published by him at Wistaston, Crewe. This is illustrated with sketches, sketch-maps, and sections drawn to the same vertical and horizontal scale, which should do much to interest the visitor to Llanberis in the many features of scientific interest that are so well displayed on Snowdon. It is a forerunner of a larger guide-book, and hence only the Llanberis path is treated as a route to Y Wyddfa. Without being didactic, Mr. Davis introduces the right touches at the right points, and gives just enough to make the reader think. The section showing the descent of the erratic maen d'ur arddu from the back of the cwm contains a lot of glacial lore, and might well be enlarged as a typical diagram of cirque-formation for the class-room. This alone is worth the sevenpence charged (8*d*. post free) for this unassuming but effective little pamphlet. Will Mr. Davis consider in the quiet of "Noddfa" whether he or his printers are responsible for "Grib Goch" (regularly repeated), "ffynon," and "carreg"?

THE latest issue of the Journal of the Royal Statistical Society (vol. lxxxiii., part iii.) contains an officer of the National Federation of Iron and Steel Manufacturers, on "The Iron and Steel Trades during the War," which brings out very clearly the efforts made by this industry to produce the enormous supply of munitions of war that were needed for the great struggle. The author makes it clear that it was the character rather than the quantity of material produced that had to be modified. Thus in 1913 the total production of pig-iron was about 10,250,000 tons, which had fallen in 1914 to just under 9,000,000 tons, and remained approximately stationary at that figure throughout the war. The classes of pig-iron used essentially for steel-making, namely, hæmatite and basic, had, however, risen from 58 per cent. to 72 per cent. of the total, by far the biggest increase being in the latter class, the output of which in 1918 was 50 per cent. above that of 1914. There was a corresponding increase in the output of steel, which reached 9,500,000 tons in 1918, an increase of 1,700,000 tons over 1914, the bulk of the increase again being in basic steel, of which there was above 50 per cent. more made in 1918 than in 1914. It is interesting to note that there were employed on the blast furnaces 39,200 men in July, 1914, as against 54,900 in July, 1919, so that the efficiency of the men employed had gone down very considerably. The total numbers employed in the industry at those two dates were 304,000 and 376,300 respectively, or, deducting those employed on blast furnaces, ironfounding, and tinplate manufacture,

which are given separately, 178,400 and 235,700 respectively, an increase of nearly one-third; by far the larger number of these were undoubtedly engaged in steel manufacture. The paper deals also with the production of iron and steel in France and in the United States, and includes an interesting table of the production and export of iron and steel in the chief iron-producing countries of the world, which shows strikingly the amount of loss that the war has inflicted upon the German iron and steel industries.

HONG-KONG Royal Observatory has recently issued its report for the year 1919, under the directorship of Mr. T. F. Claxton. The report deals mainly with meteorology, but it includes in a general way the magnetic elements and time services, with the necessary astronomical observations for the latter. In the description of the various meteorological instruments in use a doubt is thrown on the relation between the temperatures in the thermograph shelter and the hourly readings by the rotation thermometers, and it is stated that the difference is not constant throughout the day. Details of the comparison would be useful and interesting. In addition to the automatic records, eye observations of the same elements are said to be made each hour; perhaps less frequent eye observations would be sufficient, and time thus saved might with advantage be devoted to a discussion of clouds, the character and direction of which are said to be observed every three hours. Attention is directed to the large departures from normal from month to month in atmospheric pressure, temperature, and wind. A typhoon on August 22 occasioned a squall at the rate of 84 m.p.h., although the centre of the disturbance passed about 150 miles to the south-west of Hong-Kong. The greatest rainfall in twenty-four hours was 4·80 in. on July 5, and the greatest in one hour was 1·35 in. between 5 and 6 a.m. on October 1. The total rainfall for the year at the observatory was 76·14 in., of which 49·92 in. fell in June, July, and August; and in these months, in the heaviest rains occasioning floods, 38·79 in. fell in 186 hours. Seventy-one per cent. of the daily weather forecasts are said to have been completely successful. Meteorological logs were received from eighty-one ships operating in the Far East, representing 2587 days' observations. It would be a valuable asset for aeronautics if observers could be encouraged to give especial attention to cloud observations; marine and aeronautic meteorology are becoming closely interlocked.

THE June issue of *Terrestrial Magnetism and Atmospheric Electricity* contains Capt. J. P. Ault's preliminary results of the magnetic observations taken on the United States Magnetic Survey ship *Carnegie* during her voyage from Buenos Aires to St. Helena in February and March last. According to the new measurements, the deviation of the compass and the dip as given on the most recent British Admiralty Chart No. 3775 are in many cases 1° out in the deviation and 2° or 3° out in the dip. The most serious differences are to be found in the region between 45° south latitude 329° east longitude, and 36° south 354° east, where the British chart gives the deviation to the west too small by about 1°; while over the region 33° south 2° east to 16° south 8° east the dip is given between 2° and 3° too small. The horizontal intensity given on the chart is everywhere too large by about one unit in the second decimal place of the value in C.G.S. units.

THE Journal of the Torquay Natural History Society, vol. ii., No. 6, has just reached us. Among other interesting papers is one on the scientific correspondence of Charles Kingsley and William Pengelly. An account of the life of Charles Kingsley is given, together with extracts from letters written by him between 1867 and 1870 to William Pengelly. Points of natural history, mostly of a geological nature, were raised in these letters. Another paper of interest is "Mendelism and Selection." The results of recent experiments by Prof. Castle are discussed in terms of germ-plasm with the view of reconciling Mendelism with selection. In yet another paper some account is given by Mr. H. G. Lowe of the origin of the needle; its history is traced back through three needle-like implements which have been found while excavating in Kent's Cavern. The view taken is that the discovery of the needle marked the first step in man's struggle from a purely animal state of existence.

MESSRS. GAUTHIER-VILLARS, of Paris, are publishing a series of works of great men of science entitled "Les Maîtres de la Pensée Scientifique," with the object of making the original works known to scientific students. We have received four volumes containing writings of Lavoisier, Huygens, and Spallanzani, each including a short biographical note on its author. "Mémoires sur la Respiration et la Transpiration des Animaux," by Lavoisier, is a collection of four papers read to the Académie des Sciences between 1777 and 1790. The text is taken from the Mémoires of the society for the appropriate years. "Traité de la Lumière," by Huygens, is reprinted from the original work published in 1690, with some necessary alterations in spelling and punctuation. The two volumes entitled "Observations et Expériences faites sur les Animalcules des Infusions," by Spallanzani, are copies of a translation of the original work by Jean Senebier published at Geneva in 1786. The diagrams included in the translation are not reproduced. When the series is completed it will serve as a ready means of access to the works of men prominent in the history of science, and it should be particularly valuable to the student by giving him an opportunity of learning at first hand the methods and arguments by which scientific knowledge has been advanced.

MESSRS. SIFTON, PRAED, AND CO., LTD., promise for the autumn publishing season an illustrated volume by Miss Gardner King on the present condition of the inhabitants of the Fiji Islands, based upon the author's experiences among them shortly before the war. Miss King lived much among the natives in their own homes, and should therefore have an interesting story to tell.

Our Astronomical Column.

TEMPEL'S COMET.—M. Fayet has given a very probable explanation of the discordance of the Kudara observation of this comet on May 25. He finds that its true R.A. on that day was exactly 2h. greater than the Kudara one, the declination being correct. Hence the alteration of a single figure in the announcement, which may have been set down wrong by inadvertence in preparing the message for telegraphic transmission, will make everything accordant, and further explain the fact that whereas Mr. Kudara stated that the comet was visible in a small telescope, many European observers searched in vain round the position indicated. The calculated daily motion on May 25 is +3m. 34s., N. 8′, which agrees fairly well with the observed value +3m. 4s., N. 8′; the latter was probably deduced from observations extending over an hour or two. The following positions have been announced:

	G.M.T.			App. R.A.			App. S. decl.			Observer	Place
	d.	h.	m.	h.	m.	s.	°	′	″		
May	25	7	10·0	22	55	7·0	4	53	0	Kudara	Kyoto
July	20	14	5·6	1	52	49·48	1	17	0·7	Michkovitch	Marseilles
	21	13	55·4	1	55	14·44	1	18	58·5	,,	,,
	21	13	12·9	1	55	8·60	1	18	43	Mundler	Königstuhl
	22	14	35·8	1	57	37·5	1	21	2	Polit	Barcelona
	24	13	40·7	2	2	10·63	1	26	5·2	Mundler	Königstuhl

The first R.A. is conjecturally increased by 2h.

The following is a continuation of the ephemeris for Greenwich midnight:

			R.A.			S. Decl.		Log r	Log Δ
			h.	m.	s.	°	′		
Aug.	20	...	2	48	26	3	55	0·1866	9·9466
	24	...	2	52	36	4	29		
	28	...	2	56	1	5	5	0·1987	9·9428
Sept.	1	...	2	58	38	5	44		
	5	...	3	0	28	6	24	0·2112	9·9400
	9	...	3	1	29	7	5		

M. Michkovitch noted that the coma appeared round, the diameter exceeding 1′. There was a well-defined nucleus of magnitude 9·8. Dr. Palisa noted that this was eccentrically placed in the coma.

STONYHURST OBSERVATIONS IN 1919.—The annual volume of the results obtained at Stonyhurst Observatory last year contains an interesting summary by the director, the Rev. A. L. Cortie, of the solar observations. The mean spot areas for 1917–18–19 are 12·1, 7·9, and 8·4 respectively, while the mean daily magnetic declination ranges in the same years are 11·8′, 12·4′, and 12·7′. The year 1919 probably represents the hump on the downward curve, which is frequently shown both in sun-spots and variable stars. Father Cortie associates the delayed maximum of magnetic—as compared with sun-spot—activity with the declining mean latitude of sun-spots, which increases their magnetic efficiency, since it makes them cross the sun more centrally.

The most remarkable spot group of 1919 was a triple group which was on the disc from August 13 to 25 (central about August 19). A very violent magnetic storm occurred on August 11–12; if this was connected with the spot group the discharge must have been directed tangentially, not radially, from the sun. The spot group persisted through four rotations, being last seen on December 7.

The report also gives the result of a comparison between the drawings of faculæ and the photographs of calcium flocculi. A close correspondence in position is found, so that every prominent flocculus has an accompanying facula.

A research is also in progress with the view of tracing the flow of faculæ in regions of long-continued spot activity. It is anticipated that this flow will prove to be connected with the cyclonic movements that produce the magnetic field in sun-spots.

THE STRUCTURE OF THE UNIVERSE.—*Science* for July 23 contains a lecture on this subject by Prof. W. D. MacMillan, of the University of Chicago. Prof. MacMillan dwells on the numerous analogies between the microcosm of atoms and electrons and the stellar universe. For example, he shows the close analogy between the two electrons of the hydrogen atom and the sun-Neptune system, the relation between their diameters and mutual distance being about the same. He gives the number of atoms in the solar system as 6×10^{56}, and the volume of the sun's domain in the stellar universe as 20 cubic parsecs, or 6×10^{56} c.c. So that, on the average, there is 1 atom to 10 c.c., which would put the atoms about as far apart relatively to their diameter as the stars.

It will be remembered that Prof. Eddington and others have recently made the suggestion that the annihilation of atoms through collision and the consequent release of their stores of energy may be going on in the hottest stars, and thus add enormously to the duration of their output of light and heat. Prof. MacMillan endorses these speculations, and adds the suggestion that the radiant heat of the stars in its passage through space may perform the converse transformation and build up matter once more from the products of such atomic collisions, restoring to them the property of mass which they had lost. He claims as a result of these agencies to have constructed a universe that is infinite, eternal, and unchangeable. But he can scarcely claim that this conclusion is based exclusively on known facts. Many of his postulates are doubtful, and rest on analogy only.

Textile Industries and Technical Education in Canada and the United States.

PROF. ALFRED F. BARKER, of the Textile Industries Department of the University of Leeds, has written an interesting report[1] of nearly 130 pages of text, accompanied by numerous photographic illustrations, of a visit paid in the summer of 1919 to Canada and the United States. In the course of the report he discusses, among other matters, the vast resources in water-power of Canada, which, used directly or in the development of electrical energy, render to manufacturing industry an immense service, and also education and educational institutions, housing, work and wages, and industrial enterprise as they came under his observation in both Canada and the States; and he offers interesting comparisons with the conditions which prevail in the United Kingdom. Prof. Barker is, however, chiefly concerned with the extent, variety, and progress of textile manufacture connected with the production of cotton, wool, and silk goods. He was everywhere given the fullest facilities for his inquiries and investigations, with the result that his observations cannot fail to be of the highest interest and value to producers and merchants engaged in these industries.

Almost all the cotton mills in the Dominion are in the province of Quebec, attributable, Prof. Barker observes, possibly to climatic conditions, to the manipulative skill and cheap labour of the French Canadian, or to some combination of all these causes with

[1] "A Summer Tour (1919) through the Textile Districts of Canada and the United States." By Prof. A. F. Barker. Pp. xi+197. (Leeds: Printed by Jowett and Sowry, Ltd., n.d.)

other causes not so much in evidence. Many of the cotton mills are quite extensive in their buildings and equipment, and almost without exception are controlled by British or British Canadian managers, some of whom received their training in Lancashire textile schools or in those of the States. It is a unique feature of Canadian mills, as distinguished from those of Lancashire and Yorkshire, that every operation from the yarn to the finished cloth, even including the dyeing and printing, is carried out in one and the same factory, which obviously makes it much more interesting to visit than that of a similar works in this country. The woollen industry is mainly centred in Ontario, and is far less well organised than that of cotton, but the hosiery mills are in evidence in every textile district of the Dominion, and a great future lies before the industry, since the equipment and staff of workers are of the most efficient character (Fig. 1).

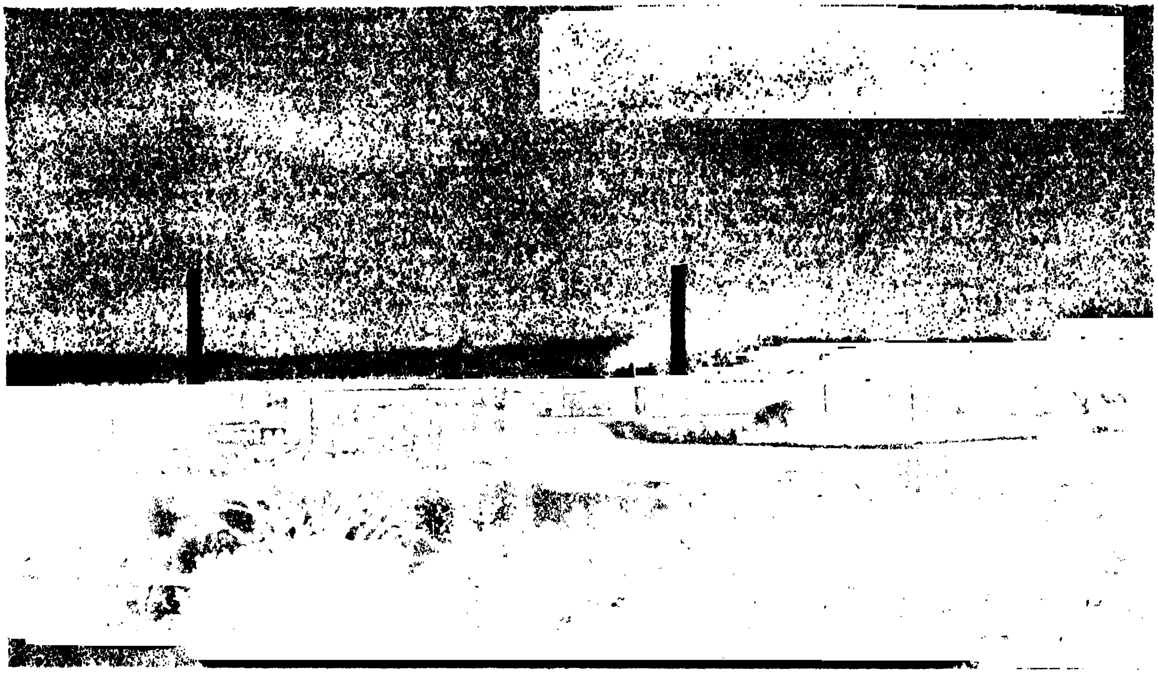

FIG. 1.—The Arlington mills, c.nsuming 200,0 o lb. of greasy woo' per day.

Referring to textile manufacture in the States, Prof. Barker remarks that fine wool yarns are now spun there which cannot be beaten in any European country, but that neither in Canada nor in the States did he see a fine cotton yarn approaching that produced by Lancashire mills. On the other hand, he visited a mill in New Jersey which produced finer and better finished dress fabrics than Bradford, and in New York he was shown worsted fabrics impossible to exceed in beauty of texture and colour.

Much space is given in the report to the subject of education and educational institutions alike in Canada and in the States. In the province of Quebec there is to be found well-equipped agricultural schools and agricultural research stations designed to serve the farming interests, whilst in Montreal, the largest city of Canada dominated by industry and commerce, there is the splendid McGill University, with its

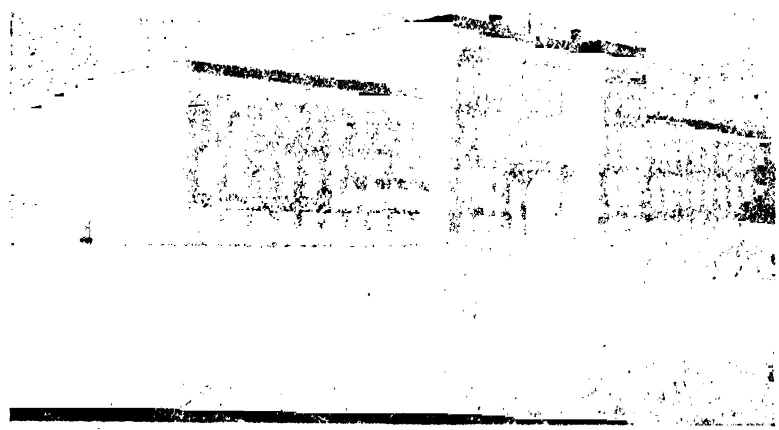

FIG. 2.—Lowell Textile School.

magnificently equipped engineering school; and in Toronto, the capital of Ontario, there is the University, beautifully situated in the park-like centre of the

city, noted for its strong Faculty of Applied Science, and not less is the city celebrated for its fine Technical High School, wherein industries and industrial processes are made to serve the highest educational purposes for its three thousand day students. At night the school is attended by six thousand apprentices in the various trades the equipment covers. In short, Canada, in proportion to its population, is well provided with institutions of university rank, and in the near future she will have educational facilities second to no other country in the world. Prof. Barker is also not less loud in his praise of the educational activities and institutions of the States, especially of the Massachusetts Institute of Technology, in many respects one of the finest institutions in the world, wherein nothing is spared to make the courses good and experimental and research work so efficient that it cannot be left out of the industrial sequence, with the result that the institution is simply flooded with students who are inspired with the possibilities of discovery. He speaks highly of the provision for textile training and education, and especially of the fine school at Lowell (Fig. 2), which represents for the textile industries what the Institute of Technology of Boston represents for mining and engineering. The report is full of apt observation upon educational and industrial aims and methods.

Sunshine in the United States.[1]

THE United States *Monthly Weather Review* for January, 1920, contains a discussion on "Sunshine in the United States" by Mr. J. B. Kincer, Meteorologist attached to the Weather Bureau, Washington, from observations mostly for the twenty years from 1895 to 1914.

Data are given showing the actual amount of sunshine in hours and tenths and the percentage of the possible amount, both methods having their special advantages. Charts and diagrams show the mean solar time of sunrise and sunset, and the average length of day, sunrise to sunset. The seasonal and annual distributions of sunshine are given in percentages of the possible amount, and a table shows for each month and for the year the percentage of possible amount of sunshine for all stations where records are made.

Some dissatisfaction is expressed at the records of the automatic instruments available, as they in no way indicate the different degrees of sunshine intensity—an anomaly shared by all other countries. In describing three forms of sunshine recorders in use, the Campbell-Stokes, the Jordan, and the electrical thermometric recorder, which is said now to be in general use by the Weather Bureau, the *Review* states: "The Campbell-Stokes burning recorder, consisting of a lens or burning-glass which scorches, during bright sunshine, a trace on a strip of cardboard placed at the proper focal distance and adjusted by clockwork to revolve with the sun"; this description seems open to objection, as the card is stationary, and the sun revolving impinges its image on the card bearing the time-scale.

Distribution of sunshine with geographical position is well treated. For the year as a whole the least amount of sunshine occurs along the North Pacific coast, where it is only 40 per cent. of the daylight hours. The maximum amount in the United States occurs in the south-west; in the Lower Colorado River valley the duration of sunshine is 90 per cent. of the total number of hours from sunrise to sunset. July is the month of maximum amount in nearly one-half of the country, including all the northern districts.

Data are given showing the average annual percentage of days clear, partly cloudy, and cloudy. Dealing with diurnal variations in sunshine, it is stated that the amount is least during the early morning hours, with a secondary minimum in the late afternoon. The greatest amount occurs near midday.

Prof. R. de C. Ward, of the Harvard University, contributed an article to the U.S. *Monthly Weather Review* for November, 1919, bearing the title "Bibliographic Note on Sunshine in the United States." Foreseeing the issue of a series of new sunshine charts for the United States, a brief account is given of previous sunshine charts issued.

Reference is made to work done by van Bebber in 1896 and by Gläser in 1912, and it is mentioned that "the available material was confessedly very inadequate." In charts prepared by Prof. A. J. Henry in 1898 the percentages of sunshine were obtained by subtracting the mean annual cloudiness from 100, and a map of normal annual sunshine compiled from observations at the Weather Bureau stations from 1871 to 1908 inclusive seems to have been obtained in the same way. The system seems open to serious objection, and is far less satisfactory than using the records of the automatic sunshine instrument.

C. H.

The Peat Resources of Ireland.

THE Fuel Research Board has issued as a Special Report (No. 2) a lecture on the above subject delivered by Prof. P. F. Purcell before the Royal Dublin Society last year. The importance of using the lower grade fuels has been greatly enhanced by the enormous rise in the price of our higher grade staple fuel, coal; and Sir George Beilby, in his introductory remarks to the Report, ascribes the revival of interest in peat as a fuel not only to the general scarcity of fuel, but also to the great and apparently permanent increase in the cost of coal.

The peat resources of Ireland are of paramount interest in that country, where the bogs cover one-seventh of the area, and Prof. Purcell estimates that the peat reserves in these bogs are more than ten times those of the *proved* coal reserves of that country. The estimated "anhydrous peat" is 3,700,000,000 tons, equivalent to 5,000,000,000 tons of average air-dried peat. Sixty-two per cent. of the farmsteads are entirely dependent upon peat fuel, and it is estimated that the annual consumption is between 6,000,000 and 8,000,000 tons.

The problem of the utilisation of peat is, as is well known, one of the economical removal of excess water, the average content of which is about 90 per cent. The effect of water is, perhaps, best emphasised when it is stated that "with 89 per cent. present, the 11 per cent. of dry peat will just be sufficient to evaporate the 89 per cent. of water." In the natural process of air-drying peat, difficulties of a practical and economic nature are met with; thus the drying season is only from five to six months. In winter, water freezing in the blocks causes their breaking down, and the whole year's supply has to be won in the limited dry season of the year. "It thus happens that a great number of hands are required for a portion of the year, and few for the remainder," and these considerations furnish a very strong incentive to the invention of economical methods of artificial drying.

In Prof. Purcell's opinion, in spite of the many methods which have been tried for the removal of

excess water and improvements in mechanical and industrial operations, the air-drying of peat by natural means is the only recognised commercially successful method in use to-day. Reduction of the water-content from 90 to 70 per cent. by pressure alone on the raw peat is considered by the author to be the maximum, and he does not consider that drying by artificial heat becomes a practical proposition until this 70 per cent. content is reached, "and even then it is a very doubtful financial proposition."

For use under boilers the water should be reduced to 30–35 per cent.; for gas producers it is stated that several leading manufacturers claim successful working with 60–70 per cent., but Prof. Purcell considers that the possibility of using peat with as high a moisture-content as 60 per cent. is doubtful, and quotes the Canadian authority, Haakel, in support. "If it were permissible [to use such wet peat] it would render the industry less dependent on the weather, extend the peat-winning season, and simplify the whole problem."

Prof. Purcell considers that a clear case for the extended development of the peat deposits exists from an agricultural point of view, for the reclamation of land by removal of the bog and drainage must add to the food-producing capacities of a country. But labour costs are no small difficulty, for, as Sir George Beilby points out in his introduction, the development of a bog with 20 ft. of good peat is in some respects analogous to the proposal to develop a coalfield of similar area containing a single seam of only 15 in. thickness. It is true that the peat bog entails only surface working, but the whole depth has to be worked and 10 tons of raw material excavated and handled for 1 ton of dry peat.

J. S. S. B.

Past and Present Sewage Systems.

TWO Chadwick public lectures recently delivered at Colchester by Mr. A. J. Martin dealt with the nature and treatment of sewage. Since the very earliest days there have been codes of sanitary laws, but all kinds of readjustments had to be made as soon as men began to congregate in large cities. These crowded conditions seem to be met most satisfactorily by the water-carriage system, by which the clean water supplied to a town returns ultimately to the sewers charged with all manner of pollution. When sewers were first laid the sewage was discharged straight into the rivers. The results were, of course, disastrous, and successive Royal Commissions were set up to find a remedy. The whole problem of sewage purification was obscure, and very little progress was made for a whole generation. Great hopes were centred in sewage farms as a method of disposing of the sewage, and the various local authorities hoped at the same time to reap a profit from the cheap manuring of the land. Sewage farms, however, rarely pay in a humid climate such as ours, for the land cannot deal with the huge amounts of water brought down from the sewers. Many other methods were tried, but in all of them the investigators failed to recognise the existence of the tiny scavengers which Nature provides to deal with our waste products.

The modern method of sewage purification was evolved after Pasteur's discovery of the bacteria which induce fermentation, and after the work of Warington and of Winogradsky on the nitrifying bacteria in the soil. The purification is carried out in two stages. The first stage is treatment in the "septic tank," through which the sewage passes extremely slowly. The solids sink to the bottom, where they are attacked by anaerobic organisms flourishing there, and ultimately either liquefied or turned into gas. The second stage of the process consists in the oxidation of the dissolved polluting matter. This matter has to be brought into contact with a large supply of atmospheric oxygen in the presence of certain small organisms which are able to oxidise the organic materials. This contact may be effected in the soil, in a specially constructed filter, or in a large volume of water. When soil forms the contact bed, purification is brought about either by "filtration," when the sewage percolates downwards through the soil, or by "broad irrigation," when the sewage merely passes over the soil surface. The method chosen depends on the openness or otherwise of the soil and subsoil. When suitable land is not available, artificial filters are made of broken clinker, destructor slag, etc. These materials provide a home for the nitrifying bacteria. The sewage is allowed to trickle slowly through, and with a good filter a purification of 80–90 per cent. is effected. When purification is allowed to take place in water, the volume of the water into which the sewage flows needs to be about five hundred times greater than the volume of the sewage.

Engineers had just settled down to the septic tank and trickling filter as the standard method for sewage purification when the "activated sludge" process was introduced by Drs. Fowler and Ardern. In this process the whole purification is completed in a tank provided with particles of activated sludge to serve as homes for the nitrifying bacteria. The sludge (*i.e.* solid deposit from the sewage) is activated by being submitted to currents of air for several days. It is then placed in the tank with the sewage, and air forced through for some hours until purification is effected. The drawback of this method is the great bulk of the resultant sludge, and the problem now is to find an economical way of disposing of the sludge so that the plant-food which is contained in sewage shall not be wasted.

Experimental Cottage Building.

IN view of the present housing difficulties, considerable interest has been centred in the results of the experiments in cottage building which have been carried out on the Ministry of Agriculture's Farm Settlement at Amesbury. These results are published in the Weekly Services for May 15 and 22, where we also learn that on Wednesdays for two or three months competent guides have been available to show visitors the experiments actually in progress. The present scheme includes thirty-two cottages, sixteen of which are for comparison purposes, and are built of brick on normal lines of construction, while the other sixteen are more directly experimental. Each cottage consists of parlour, living-room, scullery, bath-wash-house, larder, fuel store, etc., on the ground floor, with three bedrooms on the upper floor. Experiments in building in chalk include a cottage with cavity walls built of blocks made of chalk and cement, one with walls of chalk and cement rammed between shuttering, one with walls of chalk alone (chalk pisé), and one with walls of chalk and straw (chalk cob) built without shuttering. There is also one cottage of monolithic reinforced concrete and two concrete-block cottages with hollow walls. These two cottages are being erected under contract by two proprietary firms; for all the other experimental cottages direct labour is employed. The experiment also includes a pair of timber-framed cottages faced with

elm weather-boarding and two Army huts converted into permanent bungalows. With regard to the latter experiment, results show that no economy is effected by using these huts. Another cottage has walls of clay and gravel, while two single and one pair of cottages are being erected in pisé-de-terre. One of the single pisé cottages is now being roofed—this is the first two-storied pisé house erected in England.

Pisé-de-terre walls are built by ramming nearly dry soil between movable shutters arranged as a temporary mould. The method was known in England a century ago, but had fallen into disuse, and a large number of investigations have been carried out to determine the best lines for its revival. All soils are not suitable for pisé work, for not only must the particles cohere firmly when rammed and dried, but also there must be no excessive shrinkage in the drying process. Calcium carbonate helps to reduce shrinkage, while organic constituents are particularly liable to shrinkage, and therefore weaken coherence in the soil as a whole. The amount of water present in the soil at the time of use is an all-important factor. Generally speaking, this water should be between 7 per cent. and 14 per cent. of the weight of the dried earth. The most suitable method of shuttering and the best form of rammer have been decided, while experiments are also being made to find the most satisfactory material and method for rendering the exterior face of the wall. Pisé building can be carried out in the winter if there is sufficient protection from severe weather, but consideration of the expenses involved in providing tarpaulins, screens, etc., makes it evident that it is not sound economy to undertake pisé construction in the winter months. When building in pisé the foundations have to be of brick or concrete; the pisé work may be started only at about 9 in. to 1 ft. above the ground-level. This is an important factor in the consideration of the cost of pisé building, which, however, will probably prove to be a considerably cheaper process than building in brick.

Cotton Growing.

THE Empire Cotton Growing Committee of the Board of Trade, which presented its first report on cotton growing in the British Empire in January last (NATURE, February 26 and March 25), has now published a note on "Future Organisation," which may be regarded as an appendix to the report. While it is merely indicative of the trend of the Committee's ideas, in that such organisation is subject to the appointment of the director and his staff, it makes the situation more definite by estimating the probable expenditure upon the various branches of work contemplated.

As in the case of the original report, all the organisation proposed is for common service, since the expenditure can bring no direct return, but it should, in the Committee's opinion, indirectly bring about an increase in the cotton supplies. The Committee concludes that in order to carry out the work adequately an annual sum of approximately 200,000*l.* ought to be assured. This amount may appear large until we remember that cotton to the value of about 50,000,000*l.* is imported into this country annually.

The note sketches the proposals for finance and superior organisation, executive work, and the central office; for staff abroad; for supplementing staffs of agricultural departments oversea, and pioneering; for education and information; and for commercial handling. In the last case the setting up of semi-commercial experimental enterprises is excluded from the scope of the note. Amongst these headings the Committee proposes an initial expenditure of 20,000*l.* per annum upon its own research station abroad. It also proposes to provide for a staff of ninety men, including scientific workers and agricultural officers of different grades, for the purpose of supplementing local agricultural department staffs "after full consultation with and on invitation by the local administration."

Under the heading of "Education" the Committee makes proposals which take the initiative in a move towards obtaining co-operation between all the plant-using industries in order to increase the facilities for training men in pure science, later to be of economic value to the various agricultural services abroad. It estimates that university staffs in this country should be increased specially for this purpose by at least four professorships, fifteen lectureships, and six administrative and technical lectureships, together with a provision of twenty post-graduate studentships. The annual cost is estimated at 27,000*l.*, of which it is suggested that the cotton industry should contribute 12,000*l.* as its share.

Thermostatic Metal.

THE British Thomson-Houston Co., Ltd., has sent us specimens of a new bimetallic strip for use in thermostatically controlled devices. The strip is prepared by the permanent union over their entire length of two metals with widely differing coefficients of expansion. The union between the two component metals is complete and durable, and the strip may be bent, twisted, or hammered without causing the separation of the metals at any point, and even on heating the bond will not be broken so long as the temperature remains below the melting point of the softer of the two metals. Owing to this permanency of union the metal can be formed into any desired shape, annealed after formation, and safely employed at any temperature below 500° F. The component metals do not corrode under ordinary conditions, and may be used in any reasonable situation without fear of deterioration or change in operating characteristics. The amount of deflection obtained is always the same in a strip of given length and thickness for a given temperature change, and consequently the strip provides a trustworthy basis for the operation of any thermostatic device, and may be employed for work of high precision. The deflection due to temperature change varies inversely as the thickness, directly as the square of the length, and directly as the temperature change. With a strip 4 in. long, 0·31 in. wide, and 0·03 in. thick the deflection obtained for a temperature change of 100° F. is about 0·57 in. The force exerted varies as the square of the number of degrees of temperature change and as the square of the thickness, and directly as the width, and is not affected by changes of length. For a strip of the dimensions above-mentioned the force exerted for 100° F. change of temperature is about 3 oz. weight, whereas for a strip of the same dimensions but 0·1 in. thick the force exerted is about 24 oz. weight. To produce a permanent set in a strip 4 in. long, 0·31 in. wide, and 0·03 in. thick a force of about 7 oz. weight would be required. The metal is manufactured in standard sizes ranging from 0·015 in. to 0·25 in. in widths up to 6 in. and lengths up to 36 in. It can, however, generally be supplied cut to widths and lengths to suit the purchaser, and in special cases thermostatic metal parts may be completely formed to the purchaser's specifications.

University and Educational Intelligence.

CAMBRIDGE.—Last week the large theatre of the School of Anatomy was the scene of an interesting presentation to Dr. W. L. H. Duckworth, fellow of Jesus College and senior demonstrator in anatomy, on the completion of twenty-one years of devoted service to the University as lecturer in physical anthropology. This remarkable tribute to the esteem and affection in which he is held was the spontaneous desire of every demonstrator, assistant, and student to contribute some token of appreciation of Dr. Duckworth's unfailing courtesy and ever-ready help. His sympathy and charm of manner have made him one of the most approachable of teachers, and endeared him to all who have come in contact with him during his period of service. A fine inscribed silver salver was presented to Dr. Duckworth, together with a book containing the signatures of two hundred and twenty subscribers, by Dr. D. Reid on August 13 in the presence of the staff and students of the anatomy department. In addition to his brilliant academic qualities, Dr. Duckworth has shown great capacity for organisation, especially during the past year, when the chair of anatomy has been vacant and the entire control of the anatomy department has devolved upon him.

THE Dr. Jessie Macgregor prize of the Royal College of Physicians, Edinburgh, has been awarded to Miss Lucy Davis Cripps for her work on tetryl.

THE following free illustrated lectures are to be delivered in the Canada Building, Crystal Palace, at 6 p.m., under the auspices of the Institution of Petroleum Technologists:—"Oil Prospecting," G. Howell (September 1); "Petroleum Refining," Dr. A. E. Dunstan (September 8); "Utilisation of Volatile Oils," Dr. W. R. Ormandy (September 15); and "Utilisation of Heavy Oils," Prof. J. S. S. Brame (September 22).

A PROSPECTUS of the faculty of engineering of the University of Bristol, which is provided and maintained by the Society of Merchant Venturers in the Merchant Venturers' Technical College, has just reached us. Courses of study are available at the college for persons intended to engage in civil, mechanical, electrical, or automobile engineering, and particulars of these courses are given in the prospectus. The ordinances and regulations relating to degrees and certificates in engineering subjects are included, and some particulars of the Bristol sandwich system of training engineers are also given. The prospectus can be obtained from the Registrar of the University, Tyndall's Park, Bristol.

THE Bureau of Education, Calcutta, India, has issued its Report on Education in British India for 1918–19, abundantly illustrated with photographs. The terrible epidemic of influenza which broke out at the close of the year 1918 and carried off millions of people throughout India, together with the widespread failure of the crops, caused grave dislocations in the schools and colleges, though it called forth all that was best in the life and spirit of many of these institutions. The number of pupils and students in the public schools and colleges on March 31, 1918, was 7,338,663, and in private institutions 597,914—a total of 7,936,577, or 3·25 per cent. of the total population of upwards of 241,000,000 in British India alone, which percentage is nearly one-third that of Russia, probably the most backward country in Europe. The number of pupils under instruction has risen from 300,000 in 1860 to nearly 8,000,000 in 1920, and the expenditure has advanced from 200,000*l*. to upwards of 9,000,000*l*. within the same period. In 1918–19 140,000*l*. was granted for agricultural education and 60,000*l*. for technical education of a pressing nature pending the Indian Industrial Commission's report. The schools and colleges now number 162,330. One of the principal recommendations of the Calcutta University Commission, viz. the transfer of intermediate classes to the school system, has been carried out at the Patna College. Many developments show that the universities are alive to the necessity of assisting in the commercial and industrial revival. Schools of economics have been established in the Universities of Madras, Bombay, Allahabad, and the Punjab, whilst the Benares Hindu University is opening a college of mechanical and electrical engineering. Proposals for new universities at Rangoon and Nagpur are being completed, and sites have been acquired. A Bill was introduced in 1919 for a unitary university at Dacca. New outlying colleges have been opened or proposed in Bombay, Bengal, and the Punjab. Many of the colleges are said to be overcrowded with youths unfitted for an academic career, which is also borne out in the report of the Calcutta University Commission. There is immense work for education yet to be accomplished in India.

Societies and Academies.

PARIS.

Academy of Sciences, July 26.—M. Henri Deslandres in the chair.—The president announced the death of Dr. Guyon.—G. **Bigourdan**: An economical means of utilising the energy of tides.—Ch. **Depéret**: An attempt at the general chronological co-ordination of Quaternary time.—L. **Maquenne** and E. **Demoussy**: The toxicity of iron (towards plants) and the antitoxic properties of copper in presence of ferrous salts.—F. **Widal**, P. **Abrami**, and N. **Iancovesco**: The proof of digestive hæmoclasia and latent hepatism. A development of the method of detecting liver trouble described in an earlier communication. After the absorption of a glass of milk it is only necessary to determine the fall in the arterial pressure, the lowering of the number of white corpuscles, the inversion of the leucocytic coefficient, and other phenomena easily determined in the laboratory to discover the functional working of the liver. Numerous examples of the application are given, with especial reference to the disturbances caused by the administration of arsenic compounds in syphilitic cases.—A. **Perot**: Comparison of the wave-lengths of a line of the cyanogen band in the light of the sun and that of a terrestrial source. The solar wave-length is greater than the terrestrial wave-length, their difference in relative value being $(2{\cdot}22 \pm 0{\cdot}10).10^{-6}$. This difference is reduced by a correction for the descending movement of the absorbing centres to $(1{\cdot}6 \pm 0{\cdot}3).10^{-6}$. The figure calculated from Einstein's theory of generalised relativity is between the corrected and uncorrected numbers.—A. **Schaumasse**: Discovery and observations of the comet 1920*b* (Schaumasse). This comet was discovered on July 18 at the Nice Observatory. It is about the 11th magnitude, and appears as a diffuse nebulosity of 2·5′ diameter. It may be the second periodic comet of Tempel.—G. **Fayet**: Probable identity of the 1920*b* comet (Schaumasse) with Tempel's second periodic comet.—P. **Chofardet**: Observations of the periodic comet Tempel II. (Schaumasse) 1920*a*, made at the Observatory of Besançon with the bent equatorial. Three positions on July 20–21 are given. The comet was of about the 11th magnitude.—C.

Raveau: The isotherms in the neighbourhood of the critical state. The adiabatic expansion of saturated fluids.—R. **Dongier**: The point-crystal or point-metal auto-detector telephone receiver.—F. **Michaud**: The correspondence of bodies in the solid state.—A. **Pictet** and P. **Castan**: Glucosane. Glucosane was readily obtained in a pure state by heating glucose under a pressure of 15 mm. to a temperature of 150–155° C. A study of its chemical reactions leads to the conclusion that it probably has a composition analogous with ethylene oxide.—A. **Mailhe**: The catalytic hydration of nitriles. If a mixture of steam and benzonitrile vapour is passed over thoria at 420° C., benzoic acid is produced by the hydrolysis of the nitrile. The generality of the reaction has been proved by applying it to seven nitriles.—G. **Dubois**: The discovery of a fossil-bearing layer in the Flanders clay at Watten (Nord). The fauna found in this layer confirms the stratigraphical identity of London clay, Cuise sands, and Flanders clay.—A. **Carpentier**: Some siliceous fossil plants from the neighbourhood of Sainte-Marie-aux-Mines (Alsace).—L. **Blaringhem**: The heredity and nature of peloria in *Digitalis purpurea*.—R. **Souèges**: The embryogeny of the Compositæ. The first stages of the development of the embryo in *Senecio vulgaris*.—F. **Chifflot**: The gum-bearing secreting canals of the roots of the Cycadaceæ, and more particularly those of *Stangeria paradoxa*.—Em. **Perrot**: Biological notes on the Acacias producing gum, known as gum arabic, in the Egyptian Sudan.—H. **Ricome**: The action of gravity on plants.—L. **Emberger**: Cytological study of the Selaginella.—A. **Guilliermond**: New cytological observations on Saprolegnia.—G. **Truffaut** and N. **Bezssonoff**: Comparative study of the microflora and the amount of nitrogen in soils partly sterilised by calcium sulphide.—A. **Lumière**: Are vitamines necessary to the development of plants? It is generally admitted that vitamines are necessary to the growth of plants. The author, whilst admitting the accuracy of the experiments on which this view is based, considers that the experimental results have been misinterpreted. Fresh yeast, rich in vitamines and rapidly curing polyneuritic troubles in pigeons, after heating to 135° C. for one hour, completely loses all its antiscorbutic properties, but still serves for the preparation of culture fluids, giving good development of fungi. Even after heating to incipient carbonisation to 250° C. these extracts retain their fertilising properties.—A. H. **Roffo** and P. **Girard**: The effects of electrical osmosis on cancerous tumours of rats.—M. **Fauré-Fremiet**, J. **Dragoiu**, and Mlle. Du Vivier **de Streel**: The growth of the fœtal lung in the sheep and the concomitant variations in its composition.—R. **Sazerac**: Culture of the tubercle bacillus on a medium of autolysed yeast. It has been proved that both human and bovine tubercle bacilli will grow normally on this medium, the detailed preparation of which is given. It contains, in addition to autolysed yeast, 5 per cent. of common salt and 4 per cent. of glycerol.—J. **Nageotte**: Osteogenesis in grafts of dead bone.—A. **Trillat**: The influence of the presence of infinitesimal traces of nutritive substances in air-moisture on contagion.

PHILADELPHIA.

American Philosophical Society, April 23.—Dr. A. A. Noyes, vice-president, in the chair.—Dr. D. T. **MacDougal**: The components and colloidal behaviour of protoplasm. The living matter of plants is composed chiefly of mucilages and albuminous compounds in varying proportions mixed in the form of an emulsion or as a jelly. The molecules of solid matter are aggregated into groups, which also include a number of molecules of water. Growth consists of the absorption of additional water to these groups, with more solid material being added at the same time, the process being termed "hydration." The resultant increase may be detected by determination of increased dry weight or measured as increase in length, thickness, or volume. More exact studies in growth have become possible by the establishment of the fact that mixtures of 25–50 per cent. mucilage and 50–75 per cent. albumin show the hydration reactions of cell-masses of plants. It is also found that certain amino-compounds, such as histidine, glycocoll, alanine, and phenylalanine, which are known to promote growth, also increase the hydration of the "biocolloids," as the above mixtures are called.—Prof. W. J. V. **Osterhout**: Respiration. A simple method of measuring respiration has been developed whereby determinations can be made at frequent intervals (as often as once every three minutes). The application of this method to the study of anæsthesia shows the incorrectness of the theory of Verworn, according to which anæsthesia is a kind of asphyxia, due to the inhibition of respiration by the anæsthetic.—Prof. B. M. **Davis**: (1) The behaviour of the *sulphurea* character in crosses with *Oenothera biennis* and with *Oenothera franciscana*. (2) *Oenothera funifolia*, a peculiar new mutant from *Oenothera Lamarckiana*.—Prof. G. H. **Shull**: A third duplication of genetic factors in shepherd's-purse. In the third generation of a cross between a wild biotype of the common shepherd's-purse (*Bursa bursa-pastoris*) from Wales and Heeger's shepherd's-purse (*B. Heegeri*) there appeared a small number of plants of unique type, having a more coriaceous texture than in the plants of either of the two original strains involved in the cross. This new type has been designated *coriacea*.—Prof. E. M. **East**: Some effects of double fertilisation in maize.—Dr. T. B. **Osborne**: The chemistry of the cell.—Prof. G. A. **Hulett**: The relation of oxygen to charcoal.—Prof. C. E. **Munroe**: Products of detonation of T.N.T. It is known that among the products are considerable quantities of carbon monoxide, hydrogen, and some hydrocarbons, such as methane, together with free carbon in a soot-like form. Hence T.N.T. is not suitable for use in underground work or close places, because the gas evolved is poisonous and inflammable, and can form explosive mixtures with the atmosphere in these close places.—Prof. J. W. **Harshberger**: A new map of the vegetation of North America.—Prof. A. G. **Webster**: The vibrations of rifle-barrels. (Dr. H. L. Carson, vice-president, in the chair.)—Dr. L. **Witmer**: Symposium on psychology in war and education.—Dr. J. McK. **Cattell**: Methods. The speaker reviewed the development of experimental and quantitative methods in psychology, and especially the transfer of its main concern from introspection to the study of individual differences in behaviour. By co-operation with other sciences it is possible for psychology to change the environment, and behaviour can be controlled more effectively by a change in the environment than by a change in the constitution of the individual.—Dr. R. M. **Yerkes**: Psychological examining and classification in the United States Army. The initial purpose of examining was the discovery and prompt segregation or elimination of men of markedly inferior intelligence. The uses which were actually made of results of psychological examinations were extremely varied, and covered the classification of men to facilitate military training, the selection of men of superior ability for training as officers or for special tasks, the segregation and special assignment of men whose intelligence was inadequate to the demands of regular military training, and, finally, the elimination of the

low-grade mental defective.—Prof. R. **Dodge**: The relation of psychology to special problems of the Army and Navy.—Dr. J. R. **Angell**: Relation of psychology to the National Research Council. The supporting scientific societies elect representatives who compose the several divisions of the Council, and these in turn, comprising, as a rule, about twenty men selected for their eminence in their particular branch of work, come together and determine the special needs and opportunities for the improvement of research in their own fields. Special attention is paid to the possibilities of bringing about effective co-operation among research men and research agencies. Scientific investigation has hitherto been largely individualistic, and the most pressing need at the present moment is not so much the expansion of research agencies, although this is desirable, as the more effective employment of those already in existence.—Dr. B. **Ruml**: Psychological methods in business and industry.—Prof. A. J. **Jones**: The individual in education.—Prof. R. W. **Wood**: Invisible light in war and peace.

HOBART.

Royal Society of Tasmania, June 8.—Mr. L. Rodway, vice-president, in the chair.—G. H. **Hardy**: Australian Stradiomiidæ. The paper included a description of new species.—H. H. **Scott** and C. **Lord**: Studies of Tasmanian mammals, living and extinct. Part ii. The paper was divided into two sections, and dealt mainly with the skeleton of *Nototherium Mitchelli* recently obtained from the north-west coast of Tasmania. The first section gave a *résumé* of the history of the genus, and the second dealt with the osteology of the cervical vertebræ. The authors desire to show that the species was one essentially adapted for aggressive warfare. They point out that whereas the skulls of *N. Mitchelli* and *N. tasmanicum* at least (with the possibility of other species) are equally large and weighty, yet their cervical vertebræ show marked differences: one being an exaggeration of the standard of the modern wombat in about the same ratio of power (*N. tasmanicum*), while the other shows an additional power with interspinal muscles and paddings, suitable to the resisting of great shocks in the long axis of the head and vertebræ.

The Forthcoming Census.

THE Census Act of 1920 will have one great advantage over previous Census Acts—that it will be a permanent measure, and not, as they have been, limited to the operation of taking the one census that was at the time in contemplation. We have travelled far from the days when the numbering of the people was considered to be an offence that would provoke Divine anger, and it is quite time that the old hesitating policy of passing a new enactment and creating a new staff and machinery every ten years, which doubtless had its origin in consideration for those superstitious scruples, should be definitely abandoned. The system had one indirect advantage while it lasted. For the eleven decenniums since 1801 the eleven separate Acts that have had to be passed have been gradually strengthened and made more workable, as experience has shown what improvements it has been possible to introduce into the practice, and thus have ripened into the materials for a permanent statute. All the same, the necessity for organising a scratch staff of new men every ten years, and dismissing it as soon as the census work was over, has been a great drawback to the efficiency of the Department, and it is to be hoped that one result of the new Act will be to enable the Census Office so to distribute its work over the whole decennium as usefully to retain the services of an experienced and competent staff of permanent officials. Much credit is due to the successive controllers of the census for the good work they have done under all disadvantages, and it is no disparagement to them to say that they have been hampered by circumstances.

The Act contemplates, but does not require, a quinquennial census. It enacts that no census shall be required to be taken in any part of Great Britain in any year unless at the beginning of that year at least five years have elapsed since the beginning of the year in which a census was last taken in that part of Great Britain; but it leaves to the King in Council to fix the date on which each successive census is to be taken. There can be no doubt that for some statistical purposes the interval of ten years is too long, and that not infrequently in the course of that interval events arise that materially affect the applicability of averages drawn between censuses distant ten years from each other. With careful organisation a quinquennial census might be made the rule, but the Act leaves this question entirely open. It allows, however, of a special local census being made, independent of the date of the last previous census, upon the application of a local authority through the Minister of Health to his Majesty in Council for the purpose of facilitating the due performance by the authority of its statutory duties.

An important provision of the Act is that which prohibits inquiry at a census into any particulars other than those specified in the schedule to the proposed enactment. These are:—Name, sex, age; occupation, profession, trade, or employment; nationality, birthplace, race, language; place of abode and character of dwelling; education; infirmity or disability; condition as to marriage, relation to head of family, parentage, issue; and "any other matters with respect to which it is desirable to obtain statistical information with a view to ascertaining the social or civil condition of the population." The generality of this last item would no doubt be controlled by the *ejusdem generis* principle of interpretation, and there need be little fear that any Order in Council would authorise an undesirable extension of it; but care would still have to be taken against the use of the census for indirect or partisan motives. It may be stated as a general principle that the more you increase the number of items of information that you demand, the more you diminish the probability that the information you actually obtain will be accurate. A wise investigator, therefore, while naturally anxious to get all the sound information that he can, will carefully distinguish between that which is essential and verifiable, and that which cannot be relied upon.

Much light may be expected to be derived from the census returns upon subjects that have recently been prominently before the public, such as the diminution in the birth-rate, the extent to

which it has prevailed among the various strata of the community, the results of the war as affecting population and health, the effect of the shortage in housing on the general welfare, and other questions to which the events of the decade have given a new urgency; but in all these matters the principle we have just indicated of judging information, not by the number of details you are able to amass, but by the weight of accuracy and authenticity that they bear—*non numero, sed pondere*—will have to be borne in mind. The experience of the Registrar-General, backed by the enlightened enthusiasm of the Ministry of Health, will have ample exercise in these respects.

The Act is intituled "An Act to make provision for the taking from time to time of a census for Great Britain or any area therein and for otherwise obtaining statistical information with respect to the population of Great Britain." The Registrar-General, in addition to his formal Reports on the Census Returns, is to have power to supply local authorities and others concerned with statistical information derived from the census returns. The second branch of the title is provided for by section 5, which enables him also to publish statistics of the number and condition of the population derived from other sources, and for that purpose to enter into relations with other Government Departments so as to further the supply and provide for the better co-ordination of such information. If he were enabled to enter into similar relations with other countries as well, the very excellent object of obtaining uniformity in the statistics of the several nationalities might be materially promoted.

Prof. Alexander's Gifford Lectures.

Space, Time, and Deity: The Gifford Lectures at Glasgow, 1916–18. By Prof. S. Alexander. (In two volumes.) Vol. i. Pp. xvi+347. Vol. ii. Pp. xiii+437. (London: Macmillan and Co., Ltd., 1920.) Price 36*s*. net.

PROF. ALEXANDER has written a book which requires more than cursory reading. It deserves careful study. For it embodies a thoroughly modern exposition of New Realism in full detail. Moreover, these two volumes are not merely the outcome of a sustained effort at accurate investigation. They are distinguished by their admirable tone and temper. The author is throughout anxious to understand and to represent faithfully the views of those with whom he is in controversy. His reading of what has been written by the great thinkers of other schools has been closer and more intelligent than that of most New Realists, and he displays no traces of arrogance. He [illegible] all he co[illegible]reciate the material [illegible]uished, not merely [illegible] [illegible]hematical an[illegible]ical science, but by bio[illegible] [illegible]d psycholog[illegible] highly important fields for [illegible]is inquiry.

These v[illegible] merits of Prof. Alexander's method have, howev[illegible] p[illegible]duced their drawbacks. They have driven h[illegible] beyon[illegible]nt con[illegible]ptions of the New Realist[illegible]h are not always easy to reconcile with [illegible]hem. In the second volume, particularly, where the author is chiefly concerned with such problems as those of the nature of the tertiary qualities of reality, of value, and of deity, the treatment leaves the impression that the subject-matter passes beyond the limits which alone are for the method legitimate. None the less, the effort made to be consistent is a notable one. But under this head I must refer the reader to the book, for the only aspect of the doctrine in it with which space allows me to concern myself is its cardinal principle as applied to physical knowledge.

To begin with, it is necessary to be clear as to what is peculiar to himself and his school in Prof. Alexander's teaching. It is not sufficiently realised that to-day the New Realists comprise a variety of groups divided by differences that are of far-reaching importance. These differences relate to the nature attributed to mind. For some of the most prominent of the American New Realists mind has no characteristic at all that distinguishes it from its objective content. Seeing means colours occurring; hearing means sounds occurring; thinking means thoughts occurring. Mind is itself just a casual selection out of the field of consciousness, and has no nature distinct from that field. When we speak of a mind, the grouping arises out of relations possessed by the objective elements themselves, relations which exist quite independently of our own action in perceiving. Minds are thus subordinate groups in a larger universe of being which includes them, and which would be unaltered if minds disappeared from it. Consciousness is thus merely a demonstrative appellation.

Now for Prof. Alexander, and, I think, for most of the English New Realists, mind has a reality independent of its object. With the latter, whatever it is, it is "compresent." The act of perceiving is one reality, the object perceived is another. Left to itself, the activity which we call mind reveals the object, with its relations (which may be universals) just as they exist independently of it. But the activity is a separate reality, which does not belong to the ordinary object world, but reveals itself in consciousness, in which it is said by Prof. Alexander to be "enjoyed." Here

we have dualism, a dualism which he gets over by referring the origin of the activity of mind and the object with which it is compresent, alike, to a final reality which is the foundation of both, an ultimate space-time continuum. This, inasmuch as the flow of time enters into its very essence, is not static, but dynamic. The activity which we are conscious of (in the form, not of perception, which is of objects, but of self-enjoyment) is therefore in its turn dynamic, and its character is that of a conation.

I am not sure that the Americans, notwithstanding their boldness, are not here on safer ground. They project everything, thought, feeling, and tertiary qualities, such as goodness and beauty, into what they call a non-mental world. Prof. Alexander is more cautious. With him the native hue of resolution is, at times at least, as he progresses in his enterprise, sicklied o'er with the pale cast of thought. He seems to feel that he must retain something for a mental world. Starting with space and time as having no reality apart from one another, but as mere abstractions from aspects or attributes of the foundational reality, which is space-time or motion, the "stuff of which all existents are composed," he has to account for our actual experience. His foundationally existent activity breaks itself up into the complexes of which we are aware, and which possess, as belonging to their nature, certain fundamental and all-pervasive features which we recognise as categories. There result also qualities which appear in our experience. These form

"a hierarchy, the quality of each level of existence being identical with a certain complexity or collocation of elements on the next lower level. The quality performs to its equivalent lower existence the office which mind performs to its neural basis. Mind and body do but exemplify, therefore, a relation which holds universally. Accordingly, time is the mind of space, and any quality the mind of its body; or, to speak more accurately, mind and any other quality are the different distinctive complexities of time which exist as qualities. As existents within space-time, minds enter into relations of a perfectly general character with other things and with one another. These account for the familiar features of mental life; knowing freedom, values, and the like. In the hierarchy of qualities the next higher quality to the highest attained is deity. God is the whole universe engaged in process towards the emergence of this new quality, and religion is the sentiment in us that we are drawn towards him, and caught in the movement of the world towards a higher level of existence."

I have given the general result of his inquiry as summed up in the author's own words, those used by him in concluding his final chapter. But it would be unfair to suggest that the nature of this result can be appreciated from any isolated quotation. The whole book must be read. It is admirable alike in thoroughness of method and in command of material. Still, it is obvious that the entire edifice depends for its stability on its foundation, and that the author's conception of the ultimately real as being space-time, a continuum of point-instants or pure events entirely independent of mind, is the crucial point in his reasoning. If he is right, it must be in terms of this existent that all else must be capable of expression, and it cannot itself be expressed in terms of anything beyond itself. Of course, Prof. Alexander does not dispute that when we speak of space and time as of this character we are going beyond what we learn through sense, or intuitively, and are employing constructions of reflection. He is quite entitled to do this if a non-mental world can include universals, as he insists, in common with all New Realists. Our simplest experience is, as he says, "full of our ideas." The question is whether they belong to mind or to what is not mind. We shall see presently to what path this conclusion conducts.

At this stage we have to put before us the author's analysis of the relation of space to time, an analysis that seems to me altogether admirable. Space taken in abstraction from time has no distinction of parts. Time in so far as it is purely temporal is a mere now. To find a continuum we must find distinguishable elements. Without space there would be no connection in time. Without time there would be no points to connect. There is therefore no instant of time apart from a position in space, and no point of space except in an instant of time. The point occurs at an instant, and the instant occupies a point. The ultimate stuff of the universe is thus of the character of point-instants or pure events, and it is so that we get our continuum. The correspondence is, however, not a one-to-one, but a many-one, correspondence. For one point may occur at more than one instant, and one instant may, analogously, occupy several points.

Prof. Alexander thinks that he is here in full accord with Minkowski's well-known conception of an absolute world of four dimensions, of which ordinary geometry omits the fourth, the time element. When he wrote his book Einstein's doctrine of relativity was only fully known in its first form, the "special" theory, and Prof. Alexander believes that his view of the character of the space-time continuum has left him free to accept the so-called principle of relativity in this form;

For it suggests really no more than the unification of the observations of two sets of observers who may be observing an absolute world in space-time, by means of formulas of transformation in which the observations of observers with one system of co-ordinates can be rendered in terms of the co-ordinates of observers with a different system. It may be, he says, that the formulas are not really independent, inasmuch as they are ultimately numerical, and numbers may be wholly dependent on an absolute space and time system. Thus it would be an absolutely identical set of relations which was observed from the two systems of reference, moving rectilinearly with a relative velocity which remained uniform.

But can this be accepted in the fresh light cast by the general theory of relativity, of which the special theory is now shown by Einstein to be a mere special case? Here metaphysicians have to look over a fence into ground at present mainly occupied by the mathematician. But not exclusively so occupied. The ground is in truth a borderland where mathematics and epistemology trench on each other, and the fence is not of barbed wire. We are, indeed, compelled to try to do the best we can with unfamiliar topics if we would get at the truth about the nature of reality. The relativity doctrine now extends to accelerating motion. It has also, apparently, been demonstrated that a principle of equivalence obtains according to which any changes which an observer takes to be due to what he supposes to be attraction within a gravitational field would be perceived by him in precisely the same way if the observer's system of reference were moving with the acceleration which was characteristic of the gravitation at the observer's point of observation. The combination of these principles gives us relativity of measurement in actual experience without restriction. The gravitational principle is, in addition, here based, not on a supposed elementary law of gravitational *force,* whatever that means, which would leave us in metaphysical perplexities about action at a distance, but on elementary laws of the *motion* of bodies relatively to each other in a so-called gravitational field. There is no decision either for or against Euclidean geometry as a possible special case. But there is a decision that space, as a physical thing with unvarying geometrical properties, is to be banished, just for the same sort of reasons as the æther was banished before it. Only observable things are to be recognised as real in the new system of modern physicists.

It is therefore asserted by Einstein that, all motions and accelerations being relative to the system of reference of the observer, neither space nor time has physically independent objectivity. They are not measurable in themselves. They mean only the framework in which the minds of the observers arrange physical events, according to the conditions under which observation takes place. We may choose such frameworks as we please, but in point of fact we naturally choose so that the application of our method is the one that appears best adapted to the character of what we observe. The standard used will give their physical significances to our "geodetic lines." The apparent order in space and time has no independent existence. It manifests itself only in the events that present themselves as so ordered.

But the revolution in conception does not stop here. As so-called "gravitational fields" are everywhere present, the old special theory of relativity is nowhere an accurate account of phenomena. The velocity of light, for instance, cannot really be constant under all conditions. It is the things we observe in space and time that give to these their definite structure, and the relations in them of the things depend on the system of observation. To get at the fundamental law of the change which takes place in the space-time continuum we must look for the principle which governs the motion of a point in it as of the form of a differential law for the motion of such a point, not merely in a straight line in the Euclidean sense, but in a geodetic line which will be relative to any possible form of motion and acceleration in a gravitational field. If we can reach such a differential law under the aspect of an equation sufficiently elastic in its variables, we shall be able to fit into it mathematical expressions based on actual observation which give the "gravitational potentials" required for the application of the law. The form of the differential equation which expresses the law must therefore be such as to be applicable whatever may be the four co-ordinates of reference of the observer of motion in any conceivable gravitational field. The principle of equivalence necessitates this, and we get as the result a science of motion depending on the relativity of every kind of motion. All that is required is that the co-ordinates which are the variables in the equation of motion of a point-mass moving uniformly and rectilinearly should be so expressed as to be capable of transformation into the co-ordinates, whatever their shape, of any system of reference which moves in any path and has any accelerated motion whatsoever. This appears to have been done completely. The *result* is intelligible to the epistemologist who can even do no more than look across the boundary fence. The mathematical details and scaffolding he may be wholly unable to appreciate.

But not the less does he feel compelled to take off his hat reverently before the shades of Gauss and Riemann, and before those who have been able to wield the mighty sword with which these great thinkers cut the knots that held physicists back from the unrestricted calculus of to-day, purified as it now is from the old assumptions.

Now the importance of this thorough-going application of the principle of the relativity of the character of the point-event continuum to the observer is obvious. It means relativity in significance for intelligence. As Prof. Eddington has recently remarked in a notable article in *Mind*, the intervention of mind in the laws of Nature is more far-reaching than is usually supposed by physicists. He develops this conclusion in a fashion which is impressive. Freundlich and Schick in their recent books insist on the same thesis.

But what does the word "mind" mean when used thus? Not a substance in space-time, as Prof. Alexander would have it. To start with, such an assumption would involve either the rejection of the modern doctrine of relativity as the school of Einstein has put it forward as dependent on interpretation, or something tending towards solipsism. Nor can mind mean substance in another aspect, that in which Berkeley and the Mentalists have sought to display it. Few competent students of the history of thought look on philosophy as shut up to such a view, the view which New Realism seeks to bind into the "egocentric predicament."

There is another interpretation of the meaning of mind in which it signifies neither any of these things nor yet an Absolute Mind apart from that of man, but just our own experience interpreted as being in every stage relative in its presentation, and not so merely in the relation of measurement. For Einstein's doctrine seems to be only a fragment of a yet larger and even more striking view of reality. Relativity is surely not to be confined to judgments based on the co-ordinates we employ in measurement. It may equally arise in other instances from the uncritical applications of conceptions concerned with quality as much as with quantity. From such a point of view reality, including human experience, is what it is only because we are ever unconsciously, under the influence of practical ends to be attained, limiting our systems of reference, interpreted in even a wider sense than that of Einstein. These may be limiting ends imposed on us by the mere fact that we are human beings with a particular position in Nature. The relativity of knowledge will thus assume the form of relativity of the real to general points of view, and will result in a principle of degrees extending through all knowledge and reality alike, which fall short of ideal completion. It is an old principle, as old as Greek thought. If it is true, it solves many problems and gets rid of the distinction between mental and non-mental, between idealism and realism, between mind and its object. For it accepts the "that," and confines the legitimate problem to the "what." It also gets rid of the perplexing idea of an Absolute Mind as something to be conceived as apart from us while working in us.

The idea and the method, recurring as they do in ancient and modern philosophy, are worth study by those who feel the stimulus of the new atmosphere which Einstein has provided. They may find a convenient analogue to the special principle of relativity in Kant's "Critique of Pure Reason," with its investigation of the general conditions which are required in order to render any individual experience possible. If they seek for an analogue to Einstein's general principle, they may look either in the "Metaphysics" of Aristotle or in the "Logic" of Hegel. The greatest thinkers have presented resembling conclusions in varying language.

This path is one that is not easy to tread. It is as hard to enter on as is that of the metaphysician who has to try to understand the meaning for philosophy of the absolute differential equations which Einstein employs. Prof. Alexander, however, knows the direction, if he does not now look that way. And it may be that the difficulties with which the new principle of general physical relativity seems to threaten New Realism, with its non-mental and static reality, may lead him, with his openness of mind, to consider once again whether he should not wend his steps afresh towards the wicket-gate for a further pilgrimage. But whatever the direction in which he is looking, his new book is full of stimulating material, even as it stands.

HALDANE.

Principles and Practice of Surveying.

Surveying. By W. Norman Thomas. Pp. viii+536. (With Answers.) (London: Edward Arnold, 1920.) Price 31*s.* 6*d.* net.

ALL British surveyors will give the heartiest welcome to this excellent book. We have become accustomed to American and German survey literature, and have relied too much upon it. The author has gone far to relieve us of this necessity. He succeeds admirably in emphasising the importance of a due appreciation of the errors involved, and his mathematical investigations and notes on the accuracy of each method are clear and convincing.

The matter sequence is curious. We start with chain surveying and do not reach triangulation until p. 377. Surveys for purely engineering ends are often limited in extent, but none the less each method has suffered from being considered on its own merits and not as part of a whole. Geodesy and topographical surveying are barely mentioned.

We start with the field work, plotting, and area computing of chain surveys. The subject is clearly put, and the investigations of errors and of the accuracy of linear measurement are particularly valuable. It is curious to find reference in this chapter to British war maps, which owed none of their characteristics to chaining. The chapter on optics and on magnetism is welcome, though it might with advantage have gone further. After a description of instruments of minor importance and of the vernier and micrometer microscope, the author deals with theodolites, omitting mention, unfortunately, of Messrs. Watts and Co.'s latest patterns, which embody many improvements. Adjustments are fully described, and are followed by a few pages on the accuracy of angular measurements and on geodetic results.

Having already dealt with linear measurement, the author confines his description of traverses mostly to angular measurement by compass, dial, or theodolite. The investigation of errors of closure is valuable and includes an interesting mathematical analysis of Bowditch's rule. The surveyor who traverses between stations of an existing triangulation will find little help, however, for the problems which then arise are practically ignored. Two consecutive chapters deal with levels, levelling, contouring, trigonometrical levelling, and various relative and absolute methods of determining altitude. Mention is made of the Zeiss patterns of level in use on the Ordnance Survey, but there is no mention of the "water level" for contouring purposes. As usual, the student will have no excuse for failing to understand the relative values of different levelling methods. There is a brief mention of precise levelling generally, including a note on the new geodetic levelling of Great Britain. Tacheometry is thoroughly dealt with, the optics and attainable results being lucidly described, and leads on to range-finders, with special reference to the "Barr and Stroud." The chapter on plane-tabling is not so convincing as the rest, and is all too short. The plane-table has been used with success in climates as difficult as our own, and is an indispensable method of survey.

Chapters on curve ranging, earthwork calculations, and hydrographic surveying contain well-arranged information rarely to be met with elsewhere. It is under hydrographic surveying, curiously enough, that one finds a description of instrumental resection. As a subject it deserves more attention than it gets, and should not be confined to a solution from three points. Triangulation and base measurement are well dealt with and illustrated by historical references. The experienced surveyor will find little fresh information on astronomical surveying (except an interesting note on Driencourt's prismatic astrolabe), but will relish the simple and yet thorough way in which the theory is put.

The concluding chapter, on photogrammetry, deals with the photo-theodolite and contains a brief reference to stereophotogrammetry and to aeroplane photography. The get-up, printing, and paper are a pleasure to see. All surveyors should possess a copy of this book.

H. S. WINTERBOTHAM.

Australian Hardwoods.

The Hardwoods of Australia and their Economics. By Richard T. Baker. (Technological Museum, New South Wales: Technical Education Series, No. 23.) Pp. xvi+522+plates. (Sydney: The Technological Museum, 1919.)

THE author states in the preface to this work that his object is to make known to Australians and the world generally the diversity of the hardwoods with which Nature has endowed the vast Australian continent. Such a book can scarcely have been introduced at a more opportune time, when the problem of how to provide sufficient timber for the world's growing needs has become increasingly acute since the war. It is a remarkable fact that, while Australia has probably the largest variety of hardwoods in the world, covering hundreds of thousands of square miles, the number of species they represent is comparatively few—probably less than 500. Moreover, nearly half of these belong to the genus Eucalyptus, which covers at least two-thirds of the whole surface, and supplies the bulk of hardwoods required for commercial purposes.

The book is divided into three main sections. Part i. deals with the physical properties of timber, colour, grain, taste, odour, structure, weight, durability, combustibility, and other features. The author emphasises the great aid afforded by colour in the identification of Australian woods, and the fine series of chromatic plates scattered through the volume, illustrating the newly planed surface of all the important timbers, shows in a very striking manner the great beauty and variety of these woods. The writer of this notice has had an opportunity of comparing a number of these plates with specimens in the

fine collection of Australian woods at the Imperial Institute, and can vouch for their accuracy as regards both colour and delineation. Every timber has a distinct colour, though at times this is far from easy to describe in the absence of any standard colour nomenclature; in such cases coloured plates are a great help. Some of the colour terms seem to be used in a rather loose sense. The author employs eight types—(1) dark red, (2) red, (3) pink, (4) grey, (5) chocolate, (6) yellow, (7) pale, (8) white—but on comparing some of the plates we find it hard to draw the line between the types pink and pale, while some of the timbers described under the heading of white would be more correctly termed buff-coloured. The illustrations in black-and-white showing wood anatomy should also be a material aid to identification.

In part ii. we have a description of each species in botanical sequence, followed by a list of timbers arranged in grades of hardness. Part iii. contains technical articles on (i) the determination of specific timbers; (ii) nomenclature; (iii) the seasoning of timber; (iv) the preservation of timbers, concluding with an account of the economic uses of the woods. The book contains a vast amount of information useful to both foresters and students.

The typographical arrangement is somewhat open to criticism. The use of unnecessarily large types for specific names and authorities, with a wide margin, entails a great waste of space, and makes the book rather cumbersome. On the other hand, the systematic portion of the work might with advantage have been in larger type. These minor defects, however, do not detract from the general excellence of the book.

Mr. Baker is to be congratulated upon a valuable addition to the literature of Australian forestry, which should bring home to Australians the importance of preserving these many valuable woods from the extinction which threatens them by a well-devised and vigorous scheme of re-afforestation.

A. B. J.

The Columbian Tradition.

The Columbian Tradition on the Discovery of America and of the Part Played therein by the Astronomer Toscanelli: A Memoir addressed to the Profs. Hermann Wagner, of the University of Göttingen, and Carlo Errera, of Bologna. By Henry Vignaud. Pp. 62. (Oxford: At the Clarendon Press, 1920.) Price 3*s*. 6*d*. net.

IN various publications, especially in his "Histoire de la Grande Entreprise de Christophe Colomb" (Paris, 1911, 2 vols.), Mr. Vignaud has endeavoured to upset the traditional view of the discovery of America. According to that view, Columbus set out in 1492, not to discover unknown lands, but to reach the eastern parts of Asia by sailing westward across the Atlantic, having already in 1474 been encouraged to do so by the well-known astronomer Toscanelli of Florence. In this pamphlet Mr. Vignaud has again summed up the results of his studies and defended them against the attacks of his two principal opponents.

All we know about Columbus and the object of his first voyage comes from himself or his son or his blind admirer, Las Casas, and not one of these is a trustworthy witness, as the exposure of various falsehoods told about the family and early history of Columbus has proved. No trace exists of Columbus ever having spoken of going to Eastern Asia before he returned from his great discovery; but that idea is spoken of in a letter to the "Catholic Kings," which Las Casas placed as a preface to the log-book of the first voyage. This letter is, however, neither found nor alluded to elsewhere, and bears no date. In the log-book Columbus says that his sole object is *las Indias*, but that book was edited by Las Casas, and in the days when he wrote, this expression only meant the Antilles and neighbouring lands, and never the East Indies. Columbus, when leaving Palos, did not sail straight across the Atlantic, as would have been natural if his goal had been "Cipangu" (Japan), or "Cathay" (China); he first went down to the Canaries and then sailed straight westward along the 28th parallel. At 700 or 750 leagues west of the Canaries he fully expected to find land, and was greatly disturbed when none was seen, so that he must have had some private reason to believe that there were islands near that spot; and the discovery of these would seem to have been the sole object of the voyage. It has been objected to this that Columbus (according to Las Casas) carried with him credential letters for the "Great Khan." But it is known that his partner, Pinzon, had some idea of going in search of Cipangu. Mr. Vignaud suggests that it was to secure the indispensable co-operation of Pinzon that Columbus included the visit to Cipangu in his plan, but that when he only found land much further west than he had expected, he believed that what he had found was Cipangu, a belief which he kept to his dying day.

With regard to the alleged letter and map of 1474, attributed to Toscanelli, these were never alluded to by Columbus himself; and the copy of the letter found at Seville in 1871 was probably not written by him, but by his brother. The information in the letter (the map is lost) is such

as a distinguished *savant* would have scorned to supply, while it is quite in accordance with Columbus's own geographical ideas derived from the antiquated "Imago Mundi" of Cardinal d'Ailly. The letter was probably fabricated by the family of Columbus after his death to disprove the rumour that he owed his success, not to his studies in cosmography, but to some information about unknown islands privately obtained. The true glory of Columbus is that he found what he went out to find—a New World. J. L. E. D.

Our Bookshelf.

Electricity: Its Production and Applications. By Reg. E. Neale. (Pitman's Common Commodities and Industries.) Pp. viii + 136. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2*s*. 6*d*. net.

THE author addresses himself to the general reader who desires to understand something of the way in which electricity is produced and is utilised in present-day industries. The generation, distribution, and storage of electric power are first explained briefly, and then the author passes on to deal successively with lighting, heating, electric driving of machinery, traction, haulage, etc. Further chapters skim lightly over the leading features of electrochemistry, electrometallurgy, electric welding and cutting, telegraphy and telephony, and medical applications. So large a field can be covered in a little volume like this only by limitation to the barest essentials, but it is remarkable how complete and accurate is the information given. The reader is, however, hurried on unpleasantly fast, and is never allowed to pause where his interest is aroused. We are not as a rule over-fond of "tabloid" education, but the ubiquitous use of electricity in industry and daily life makes it desirable for everyone to know something of its nature and scope. It will be an advantage to many to have at their disposal so well compiled a summary of the subject rather than to rely on the loose statements too often made in conversation and in the non-technical Press.

The Nature-study of Plants in Theory and Practice for the Hobby-Botanist. By T. A. Dymes. Pp. xviii + 173. (London: S.P.C.K.; New York: The Macmillan Co., 1920.) Price 6*s*. net.

THE first part of this book is devoted to an explanation of the meaning of the phenomena of plant life and its interdependent functions. Wherever possible, comparisons are drawn with human life, and, in consequence, chapters are given curious titles, such as "Marriage" and "Settling Down for Life." The second portion of the book is a detailed account of the life-history of the Herb Robert and its relatives. Tables are appended showing the separation of the sexes in time, the mode of pollination, and the method of seed dispersal of British species of Cranesbills and Storksbills. The book should be a stimulus to intelligent and intensive Nature-study.

Eugenics, Civics, and Ethics: A Lecture delivered to the Summer School of Eugenics, Civics, and Ethics on August 8, 1919, *in the Arts School, Cambridge.* By Sir Charles Walston (Waldstein). Pp. 56. (Cambridge: At the University Press, 1920.) Price 4*s*. net.

A STRONG plea is made in this lecture for the organisation and development of the study of ethics, or, as the author prefers to call it, ethology. The interdependence of eugenics and civics, and the foundation of both in ethics, are discussed, and warning is given against striving to produce the perfect physical specimen of man without due consideration of character and mental attributes. Towards the end of the lecture the progressive nature of ethical codes is made clear, and great stress is laid on the importance of the establishment of our ideal of the perfect man and the teaching of such practical ethics in both schools and homes.

A Second Book of School Celebrations. By Dr. F. H. Hayward. Pp. 133. (London: P. S. King and Son, Ltd., 1920.) Price 5*s*. net.

"A FIRST BOOK OF SCHOOL CELEBRATIONS" was reviewed in NATURE for August 5. The new volume contains a further series of celebrations dealing with the military conflicts in Palestine, toleration, Alfred the Great, Pasteur and Lister, Sir Philip Sidney, G. F. Watts, Empire Day, political parties, school leaving day, work, and five of a new type, termed by the author "homage celebrations," which deal with the artist, the martyr, the musician, Ireland, and Poland.

Stories for the Nature Hour. Compiled by Ada M. Skinner and Eleanor L. Skinner. Pp. 253. (London: George G. Harrap and Co., Ltd., 1920.) Price 5*s*. net.

A NUMBER of short stories from the pens of many authors have been collected in this volume. Hans Andersen, Ruskin, and Charles Lamb are represented, and the compilers themselves have supplied eight legends. The book should be useful to the teacher giving lessons on natural history subjects to small children, and should also make interesting reading for older children.

A Manual of Elementary Zoology. By L. A. Borradaile. Third edition. Pp. xviii + 616 + xxi plates. (London: Henry Frowde, and Hodder and Stoughton, 1920.) Price 18*s*.

THE last edition of this work was reviewed in NATURE for April 3, 1919. The only important change made in the new edition is the inclusion of twenty-one large plates, most of which are particularly valuable for laboratory work. Plate xii, showing various breeds of British sheep, is crude, and seems unworthy of a place in a book which is otherwise remarkable for its clear diagrams and realistic illustrations.

Le Radium: Interprétation et Enseignement de la Radioactivité. Par Prof. Fr. Soddy. Traduit de l'Anglais par A. Lepape. (Nouvelle Collection scientifique.) Pp. iii+375. (Paris: Félix Alcan, 1919.) Price 4.90 francs.

THE third edition of Prof. Soddy's book, "The Interpretation of Radium," which was reviewed in NATURE for February 20, 1913, is the original from which this translation was made. The translator has added an appendix in which the work of the period 1914–19 is described, and consequent modifications of theory are indicated.

Grasses and Rushes and How to Identify Them. By J. H. Crabtree. Pp. 64. (London: The Epworth Press, n.d.) Price 1s. 9d. net.

THIS little book is a catalogue of all the grasses and rushes of the English countryside. A brief description, accompanied by an illustration, is given of each plant mentioned. The book should be of value to both farmers and students.

Experiments with Plants. A First School-book of Science. By J. B. Philip. Pp. 205. (Oxford: At the Clarendon Press, 1919.) Price 3s. net.

MOST of this book is devoted to the experimental study of the elementary physiology of seeds and plants. An account of the reproductive process is included, and the elementary physics and chemistry of soils are briefly indicated. In the appendices a sketch is given of the scientific principles which are necessary to a study of botany. An index would have been a useful addition to the book.

Aluminium: Its Manufacture, Manipulation, and Marketing. By G. Mortimer. (Pitman's Common Commodities and Industries.) Pp. viii+152. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

THIS interesting book gives a particularly good account of the numerous applications which aluminium now finds in modern industry. The technical processes for the extraction of aluminium and its adaptation, both in the pure state and in the form of alloys, to industry are carefully and fully described. The book is well illustrated, and cannot fail to be of interest to chemists, engineers, and the general reader.

Chemical Theory and Calculations: An Elementary Text-Book. By Prof. F. J. Wilson and Prof. I. M. Heilbron. Second edition. Pp. vii+144. (London: Constable and Co., Ltd., 1920.) Price 4s. 6d. net.

THIS is an admirable collection of problems covering a wide range, and including many of an advanced character. A pleasing feature is the brief but lucid account of chemical theory, including a short section on atomic numbers. The book should prove of great service to teachers and to students preparing for degree examinations. It is distinctly better than most books on chemical arithmetic, since it aims at a higher standard.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can be undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

University Grants.

I AM glad to see that the very urgent necessity for the provision of increased University grants which was so ably stated in your leading article of August 5 has led to the position in Leeds and Birmingham being brought forward so clearly by Sir Michael Sadler and Principal Grant Robertson in NATURE of August 12 and 19. There can be no doubt that every university in the country is feeling the need of largely increased financial assistance, without which it will be impossible to carry on efficiently, if at all, departments such as those of science, which must always be a source of large expenditure and financial loss to any university.

It is probably generally true that the higher the efficiency of a department, the greater is its cost of maintenance, and, consequently, the greater the financial loss to the university. Therefore, so long as reasonable economy in administration is practised, the expenditure of money on a successful department should be welcomed and encouraged, and every effort made to provide funds so that its work may have free scope and not be hampered in any way. Only under conditions of proper equipment as regards both staff and material and freedom from financial worry can a department be expected to develop to its fullest extent and to produce knowledge.

In the *Times* of August 18 Prof. Soddy and I directed attention to the critical condition of science at Oxford, and pointed out that there is actually no proper accommodation here even for the teaching of physical and inorganic chemistry. The antiquated buildings which are now used for the purpose are quite out of date, besides being far too small to cope with the large number of students who are presenting themselves for the honours degree.

The case of organic chemistry is also very serious because, although the laboratory which was built four years ago, largely owing to the generosity of Dr. C. W. Dyson Perrins, is modern and well-equipped, it is far too small.

A new extension is in course of construction, but the funds necessary to pay for it are not available, and must be borrowed, and there is, moreover, no adequate endowment to provide for upkeep when the buildings are completed. A similar state of things is to be found in connection with the new chair of biochemistry recently endowed through the generosity of Mr. Edward Whitley. There are no laboratories associated with this chair, and in the meantime accommodation must be provided in the already overcrowded physiological laboratories. A careful estimate of the cost of urgently required new buildings shows that at least 250,000l., as well as an endowment bringing in 10,000l. per annum, must be forthcoming if the study of chemistry is to be placed on a firm basis in this University.

I have dealt more particularly with chemistry because it is generally admitted that the most pressing need in this University is that chemistry shall be placed on such a footing that teaching and research may be done under conditions very different from those which prevail at the present time. But the other branches of physical science are also urgently in need of financial assistance, partly for new build-

ings and partly to provide funds sufficient to maintain and work them.

There are clearly only two sources from which the very large sums required by the universities can be obtained, and those are (1) Treasury grants and (2) private benefactions.

You have pointed out that the proposed Treasury grant of 1,500,000*l.* included in the Estimates for 1921–22 is quite inadequate, and it is obvious that this must be the case. It is, therefore, to be hoped that careful inquiry into the needs of the universities by the Treasury will result in this sum being substantially augmented. With regard to private benefaction, I think we may look forward with confidence to very liberal response in the near future from generous individuals, and more particularly from wealthy firms interested in the progress of science and education. The action of Messrs. Brunner, Mond, and Co. in setting aside 100,000*l.* as a contribution to the universities is an example which will certainly be followed by other firms who owe much of their success to the work of chemists, engineers, and others sent to them from the universities.

If it were to become a recognised practice for firms who can afford to do so to set aside yearly some comparatively small sum as a contribution to the universities, the combined effort would go far to solve the difficulties in which we find ourselves at the present time.
W. H. PERKIN.

The University Museum, Oxford, August 22.

Use of Sumner Lines in Navigation.

MAY I venture to point out, in the interests of navigational science, that although the article by Capt. Tizard in NATURE of July 1 under the above title is an admirably clear and concise account of the application of Sumner lines in navigation at the date given in his examples, it is scarcely descriptive of the best practice of to-day?

Of the two methods of drawing the lines described by Capt. Tizard, the first, or "original Sumner method," is now merely of academic interest, and is seldom practised outside schools and examination-rooms. Its defects are, first, that each sight has to be worked out twice (once for each of the two assumed latitudes), and, secondly, that it is inapplicable to sights taken near the meridian. It may also be remarked that unless the two assumed latitudes are very close together, the true circle of position may differ considerably from the straight line joining the two points found on the Mercator chart.

The second method described by Capt. Tizard, usually known as the "chronometer method," is still used to some extent. It avoids the double working out of each sight, but gives good results only for observations taken on large bearings; it is inapplicable to sights taken near the meridian.

For observations near the meridian what is called the "ex-meridian method" may be used to draw the position-lines. In this method the longitude is assumed, and the sight is worked out as a latitude observation; the position-line is then drawn, at right angles to the bearing, through the point where the meridian of the assumed longitude is cut by the parallel of the observed latitude. This method gives good results for sights near the meridian, but fails on large bearings.

A combination of the last two methods is sometimes employed, the sights near the meridian being worked out by the "ex-meridian method," and those on large bearings by the "chronometer method." This combined procedure has been advocated by several writers, especially by Capt. Blackburne, who undertook the immense labour of computing tables specially adapted for the purpose. The main objection to it is that the procedure is not uniform for all sights.

A much better method of drawing the Sumner lines than any of the above, and one which seems destined to replace all others, being now in extensive use by navigators of all nations and recognised as the standard method in the Royal Navy, is known as the Marcq Saint-Hilaire method, or the "new navigation." It consists in assuming a dead-reckoning position in both latitude and longitude, and then finding how much the observed zenith-distance of a heavenly body differs from that calculated on the assumption that the dead-reckoning position was correct. The difference between the observed and calculated zenith-distances is laid off from the assumed position in a direction to or from the observed object (according as the observed zenith-distance is less or greater than the calculated one), and the position-line is then drawn through the point so found at right angles to the bearing. The great advantage of this method is that it is perfectly *general*; it gives equally good results whatever the bearing of the object sighted.

Though called the "new navigation," the Marcq Saint-Hilaire method of drawing the Sumner lines is by no means a recent invention, having been used in the French Navy for more than forty years. Its advantages were advocated so long ago as 1888 by that indefatigable worker for the advancement of navigation, the Rev. William Hall, R.N., and have since been frequently pointed out by other English writers on navigation. Its superiority over all other methods for drawing the Sumner lines or position-lines being indubitable, there is a little difficulty in understanding its comparative neglect by British navigators up to recent times. One reason, no doubt, is conservatism; the British seaman usually prefers to use time-honoured methods with which he is familiar rather than to adopt new-fangled notions, and fears to risk his ship by the possibility of making a mistake in a process with which he has not been made acquainted during his early training. Another reason which operated powerfully until within the last twenty years or so was the absence of any tables for facilitating the calculation of altitudes comparable in scope with the tables of Davis and Burdwood, which so greatly helped in the rapid reduction of sights by the "chronometer method." This last difficulty was removed by the publication of the excellent "Altitude Tables" of my namesake, the Rev. F. Ball, M.A., of the Royal Navy, and at the present time it is just as simple a matter to work out sights by the "new navigation," with the aid of these tables, as it was to work the old "chronometer method" with the help of Burdwood and Davis.

Until within the last decade it was seldom worth while to attempt to fix a ship's position at sea within a mile or two, because so long as the longitude, whether found by Sumner lines or by any other method, was dependent entirely on the Greenwich time as found by the transport of chronometers over long distances, it was usually impossible to be sure of the longitude within that amount, no matter how accurately star observations were made. This difficulty affected the hydrographic surveyor as well as the navigator; and, indeed, it provides the explanation why so many charted longitudes—down the Red Sea, for instance—are in error by a mile or more. But nowadays, when wireless time-signals enable the error of a ship's chronometer to be found daily with an accuracy of a few tenths of a second anywhere on the seas, there is no reason why the longitude should

ever be uncertain by so much as the tenth of a mile, provided only that sights can be taken with a corresponding degree of accuracy. Thus the advent of wireless telegraphy, by removing at one stroke the most serious of all pre-existing limitations to precision in the results, has made it worth while to improve the methods of position-finding at sea. Simultaneously progress has been made in the construction of charts and instruments adapted for navigation, giving to the navigator another stimulus towards attaining that refinement of method by which alone he may hope to steer his ship from port to port not only in safety, but also with that economy of time and fuel which is demanded by modern competition.

As regards the number of position-lines required to determine a ship's position, it is obvious that if only two sights are taken, no matter how favourable the angle at which the position-lines cut each other, the position found will be correct only if the observations are free from instrumental and other errors, and if dip and refraction are correctly allowed for. With only two sights a large unknown centring error in the sextant employed, or abnormal refraction, or a mistake in one of the sights, may render the position found quite false, and there is no means of detecting the error. If the two sights are not simultaneous or nearly so, there will, of course, be an added uncertainty in the position due to the difficulty in accurately estimating the ship's run in the interval. If *three* sights are taken constant errors can be eliminated, but accidental errors cannot be readily detected. If *four* sights are taken, however, as nearly as possible simultaneously, on bearings differing by approximately 90°, not only will a constant error of even two or three minutes in the measured altitudes, or in the allowance for dip, be without influence on the accuracy of the result, but if a mistake has been made in one of the sights the fact can readily be detected. This is a powerful argument for making the astronomical determination of a ship's position depend, whenever possible, on at least four Sumner lines or position-lines deduced from observations of four stars differing by approximately 90° in bearing.

It can easily be proved geometrically that when the altitudes of three or more stars have been equally accurately observed, the most probable position is the centre of that circle which most nearly touches all the position-lines, and in which the directions of the stars from the points of contact are either all towards or all away from the centre; also, that the radius of the circle gives the amount of any constant error in the observed altitudes, whether due to errors of the sextant employed or to error in the assumed dip of the horizon or refraction. If with more than three sights no circle can be drawn satisfying the condition of approximately touching all the position-lines, while at the same time having the star-directions from the points of contact pointing either all towards or all away from its centre, then it is certain that a mistake has occurred in one or more of the observations; either an altitude or a time has been wrongly recorded or one of the stars wrongly identified, or else there has been a mistake in the calculation for one or more of the sights.

The importance of considering the directions of the stars, as well as the position-lines themselves, is well illustrated by reference to the first of the examples given by Capt. Tizard. If the non-intersection of the three position-lines in his Fig. 1 is due to a constant error in all the altitudes, caused either by instrumental error or by error in the tabular allowance for dip or refraction (as will usually be the case in sights taken by a practised observer), then the true position is not, as might at first be thought, within the little triangle formed by the crossing of the lines, but *outside it*; and the true longitude is not 145° 4', as Capt. Tizard concludes, but 145° 5'. For, as will be seen by Fig. 1, on which I have indicated the star-directions by arrows, no other circle than the one shown can be described so as to touch all three position-lines, while the three star-directions from the points of contact point either all towards or all away from its centre.

So great is the importance of accuracy in the fixing of the ship's position at sea in modern navigation, and so well is the "new navigation" with four position-lines crossing at about 90° adapted to secure this accuracy, that at the recent International Hydrographic Conference in London it was proposed by an eminent authority, Comdr. Alessio, of the Royal Italian Navy, that it would be desirable for the conference to prescribe as a fundamental rule of navigation that "the normal astronomical determination of a ship at sea must be made with the method of four Sumner lines by observing four stars the position-lines of which cut at approximately 90°." It was decided that the prescribing of rules for navigation did not fall within the scope of the 1919 Conference,

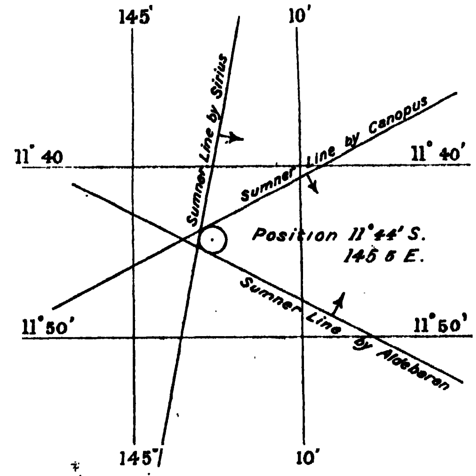

FIG. 1.

and consequently the matter was not further discussed. But there can be no doubt that if navigators of all nations could be persuaded to follow so excellent a rule as that suggested by Comdr. Alessio, it would add greatly to the safety of shipping. The method is so simple, and affords such security against error, that if it were once systematically taught in schools of navigation and included in the Board of Trade requirements for masters' certificates, it would probably by its own merits displace all other processes for fixing positions at sea under normal conditions. It would, of course, still be advisable to retain the ordinary meridian or ex-meridian sights for latitude and the morning or afternoon sights for longitude as a stand-by against the possibility of clouds or fog interfering with the twilight observations of stars, but whenever the suggested rule could possibly be followed it could be trusted to give far more accurate results than any observations of the sun.

A word may perhaps be added as to the manner of calculating the altitudes in the "new navigation." Comdr. Alessio (Report of the International Hydrographic Conference, London, 1919, p. 230) recommends logarithmic calculation with five-place tables,

using a formula which permits of a ready check. This only takes about five minutes for each sight, and is, no doubt, the best way; in fact, it is the only safe way where a very considerable degree of precision is aimed at. But most navigators prefer to avoid computation so far as possible by the use of tables, and in ordinary circumstances the altitude tables used in the Royal Navy will give sufficiently accurate results. The great defect of the tabular method is that one has to round off the dead-reckoning latitude to the nearest degree for the assumed position in order to enter the tables, and consequently the position-lines may extend over so great a distance on the chart that their curvature cannot properly be neglected. With logarithmic calculation, on the other hand, the actual dead-reckoning position can be taken as the assumed position, and the position-lines will then be so short that their curvature can be neglected without any perceptible loss of accuracy.

It may not be out of place to remark in conclusion that the utility of the Sumner line or position-line principle is not confined to position-fixing with a sextant at sea. I have shown in two recently published papers ("Notes on the Working of the New Navigation," Cairo, 1918, and "The Prismatic Astrolabe," *Geographical Journal*, July, 1919, p. 37) that the "new navigation" is capable of useful application on land in conjunction with theodolite observations and wireless time-signals, and that determinations of geographical position of very considerable accuracy may be made in this way. The method has since been put into practice by Dr. Hamilton Rice on exploratory land surveys in South America (see the *Geographical Journal* for July, p. 59) with satisfactory results.

JOHN BALL.

Survey of Egypt, Cairo, July 24.

Relativity and Hyperbolic Space.

OBSERVATION tells us that while gravitation dominates the history of a lump of matter moving in the vast ocean of free æther, it has practically no effect on the history of a pulse of light in similar circumstances. Since last mail I have investigated the bearings of space being hyperbolic on light-rays.

The central-projection map of the space, used before, in which $r=\tanh\Theta$, where r is the radius vector of the map and $R\Theta$ the radius vector in the space, will be called a gnomonic map; planes are mapped as planes. If the projection used be given by $r=2\tanh\frac{1}{2}\Theta$, the map will be called stereographic; small regions are mapped in correct shape, spheres and planes as spheres, and the two sheets of a pseudo-sphere as two spheres intersecting and making equal angles with the sphere representing the median plane, in a circle lying on the absolute, $r=2$. (A pseudo-sphere is the locus of a point at a given distance from a given plane, called its median plane. The characteristic of the map-sphere which represents a plane is that it cuts the absolute $r=2$ orthogonally.) A point (x, y, z) on the gnomonic map becomes $[x/(1+\frac{1}{4}r^2), y/(1+\frac{1}{4}r^2), z/(1+\frac{1}{4}r^2)]$ on the stereographic map.

The behaviour of a ray of light is fully described by saying that its path on the gnomonic map may be put in the form $x^2/a^2+y^2=1$, where a is less than 1, and that the eccentric angle is t/R, where t is co-ordinate time. This ellipse really represents the two branches of a pseudo-circle; the ray goes out to infinity (in the space) along one branch and returns along the other, the complete circuit having the period $2\pi R$. The median line of the pseudo-circle passes through the origin—that is, through the observer.

If from a given point rays start in all directions there will be a definite wave-front. For a finite time before t attains the value of a quarter-period, $\frac{1}{2}\pi R$, this front will form the single sheet of a true sphere the centre of which recedes to infinity, whereupon the front develops the two sheets of a pseudo-sphere, the one proceeding in the same direction as before, and the other, together with the median plane, returning from infinity, having been reflected back by the absolute. By the time $t=\frac{1}{2}\pi R$ the median plane has just reached the origin, and the reflected sheet is chasing both the other sheet and the median plane back on the way to infinity. In the next quarter-period these motions are reversed in order of time, in direction of motion, and in position relative to the origin. At the time $t=\pi R$ the front has contracted down to a point focus situated on the opposite side of the origin from the radiant point at a distance equal to that of the point. At the time $t=2\pi R$ the original circumstances recur, and everything is about to be repeated. A ray always moves normal to the front, although the centre of the true sphere and the median plane of the pseudo-sphere themselves move from and to infinity in a finite time.

All these motions can be exactly imitated in Euclidean space. Let, at a given point in such a space, the velocity of light be $1+r^2/4R^2$, the same in all directions, and let the sphere $r=2R$ be a perfect reflector. Then light will in this medium behave exactly as does the light in the stereographic map (when the scale of that map is increased in the ratio of R to 1). Indeed, this seems the easiest method to get the differential equation of the path of a point in the hyperbolic space, for which $\int dt$ is stationary. I may remark, however, that when the equation is obtained, later work is much simplified by changing the dependent to a form corresponding to the gnomonic map.

In the stereographic map the rays after an even number of reflections, by the absolute, form a system of coaxial circles through the radiant point and that point on the *opposite* side of the origin which is inverse to the sphere $r=2$. (For radiant point let $0=x-a=y=z$. Then for the second point mentioned it is meant that $0=x+4/a=y=z$. Ordinary inverse point would be $0=x-4/a=y=z$.) After an odd number of reflections they are similarly related to the focus mentioned above. The fronts are the spheres cutting these coaxial circles orthogonally.

The Antarctic Anticyclone.

IN NATURE for August 5 Mr. R. F. T. Granger remarks: "The same conditions, *i.e.* the surface outflow and the central descent of air, exist in Prof. Hobbs's polar ice-cap anticyclone; the only difference is the physical origin."

In the case of the ice-cap there are other differences as well; the temperature is lower in the case of an ice-cap than in an anticyclone. The ice-cap conditions which resemble those of an anticyclone are, as Mr. Granger says, "surface outflow and the central descent of air." The differences are low temperature, low pressure, and different physical origin. My suggestion was that these differences made it inadvisable to call them both anticyclones.

A Method of Reaching Extreme Altitudes.

By ROBERT H. GODDARD, Professor of Physics, Clark College, Worcester, Mass.

IT is the purpose of the present article to state the general principles and possibilities of the method of reaching great altitudes with multiple charge rockets, from which the exploded gases are ejected with high efficiency.

Fundamental Principle.

The basic idea of the method, briefly stated in general terms, is this: Given a mass of explosive material of as great energy content as possible, what height can be reached if a large fraction of this material is shot downwards, on exploding, with as high a speed as possible? It is evident, intuitively, that the height will be great if the fraction of material that remains is small and the velocity of ejection of the gases is high.

A theoretical treatment of the subject shows that, provided the speed of ejection of the gases is high, and the proportion of propellant is large, the initial masses necessary to raise a given mass to great heights are surprisingly small, but are enormously large if these conditions are not satisfied.

Principles to be Applied in Practice.

(1) In order to apply practically the general principle above stated, there are three conditions that must be realised experimentally: First, the gases produced by the explosion must be ejected downwards with the greatest efficiency possible. This requirement must be met by burning the explosive in a strong combustion chamber, to which a tapered nozzle is attached, in order to obtain the work of expansion of the gases.

The apparatus used in the first experiments is shown in Fig. 1, in which P is the charge of dense smokeless powder, and B is the wadding. Three steel plugs were used, to vary the size of the powder chamber. The velocity of the gases

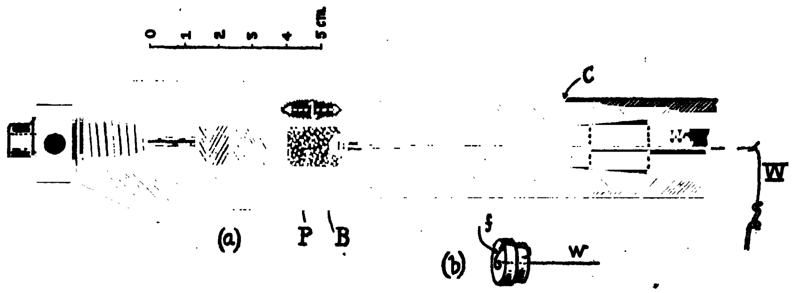

FIG. 1.—Chamber used in early experiments.

was measured by supporting the chamber in a ballistic pendulum, and observing the motion of the recoil.

It was found, by experiment, that the energy of motion of the ejected gases as compared with the heat energy of the powder could be increased very greatly over that for ordinary rockets, the highest velocity being nearly 8000 ft.-sec., produced by the chamber shown in Fig. 2, whereas

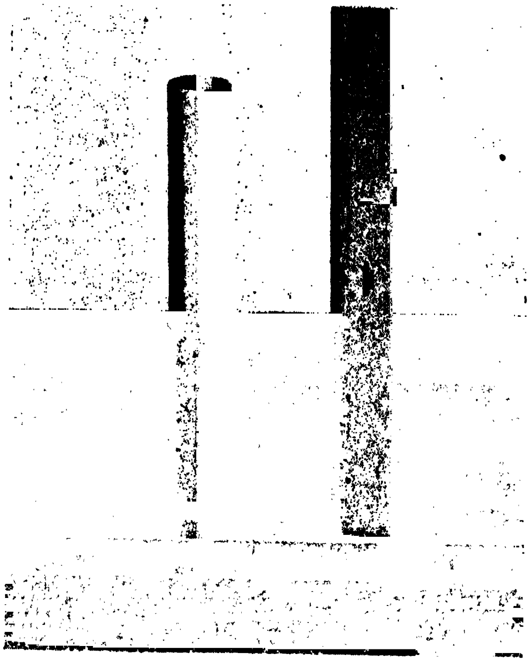

FIG. 2.—Chamber by which ejected gases were given a velocity of nearly 8000 ft. per sec.

for ordinary rockets the velocity is but 1000 ft.-sec. Incidentally, the energy of motion of the gases in the case under discussion is more than 64 per cent. of the heat energy of the powder, whereas for ordinary rockets the efficiency thus defined is but 2 per cent.

An interesting way of emphasising the magnitude of the velocity, 8000 ft.-sec., is to compare it with the "velocity of escape," or the "parabolic velocity" of planets. This velocity of escape is the velocity a body would require, projected upwards from a planet, in order to escape to infinity, and is a perfectly definite velocity, depending only upon the mass and diameter of the planet. For the moon the velocity is 1·5 miles per second, and for the planet Mars 3·0 miles per second. Thus if the chamber shown in Fig. 2 were placed upon the surface of the moon

and fired, ***most of the gases would escape from the moon's attraction.*** The highest velocity gases would without doubt (since 8000 ft.-sec. is only the *average* velocity) escape from Mars, if the planet had no atmosphere.

It should be remarked that, as shown by experimental results, the best form of nozzle has not yet been made, so that even 8000 ft.-sec. can be exceeded by further research.

(2) The heavy chamber, as mentioned above, while permitting high velocities of the ejected gases to be obtained, would be an actual disadvantage if a single charge were to be fired,

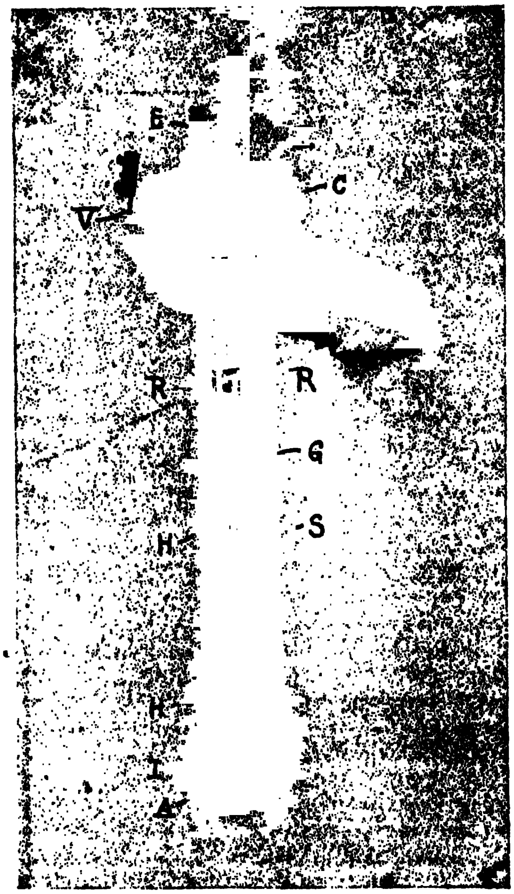

FIG. 3.—Chamber held in a support to test influence of air upon the propulsion of a rocket.

because of the large weight. It is necessary, then, that some means should be employed whereby *charges may be fed successively into the same combustion chamber.* If this is done it is evident that *most of the rocket can consist of propellant,* which is one of the conditions necessary for the attainment of great altitudes.

(3) When the magazine containing the charges just mentioned is nearly empty, it is easily seen that the propellant is no longer a large fraction of the entire mass of the apparatus. Hence, in order that the fraction shall remain large, it is necessary that one or more rockets, really copies in miniature of the larger primary rocket, should be used if the most extreme altitudes are to be reached, in order that the above fraction will, *at no time during the ascent,* become small.

Summary of Results to Date.

The theoretical work, done at Princeton University in 1912, was not followed by experimental tests until 1915, at Clark University. The work has since been continued at Clark University, in the magnetic laboratory at the Worcester Polytechnic Institute, and at the

FIG. 4.—Pipe into which chamber was fired to a tank exhausted to a low pressure, the gases moving in a circular path until stopped by friction.

Mount Wilson Observatory in California—for the greater part of the time under a grant from the Smithsonian Institution.

The results of this work have shown, first, that most of the heat energy of even so powerful a propellant as dense nitroglycerine smokeless powder can be converted into kinetic energy of the ejected gases. They have demonstrated, secondly, that a multiple-charge rocket can be made which will fire several charges in succession, is light and simple, and travels straight.

In order to demonstrate whether or not the rocket depended for propulsion upon the presence

of air, a large number of experiments were performed in which the chamber, Fig. 1, was held in a support, Fig. 3, and fired in a 3-in. pipe, P, on a large tank, Fig. 4, exhausted to a low pressure. These experiments demonstrated that the presence of the air was not necessary for reaction and that *the recoil is produced by reaction from the high-velocity gases* that are ejected. The operation of the jet *in vacuo* need not appear mysterious if one thinks of the ejected gases as a charge of fine shot moving with a very high velocity. Obviously the chamber will react, or "kick," when this charge is fired, exactly as a shot-gun "kicks" when firing a charge of ordinary shot.

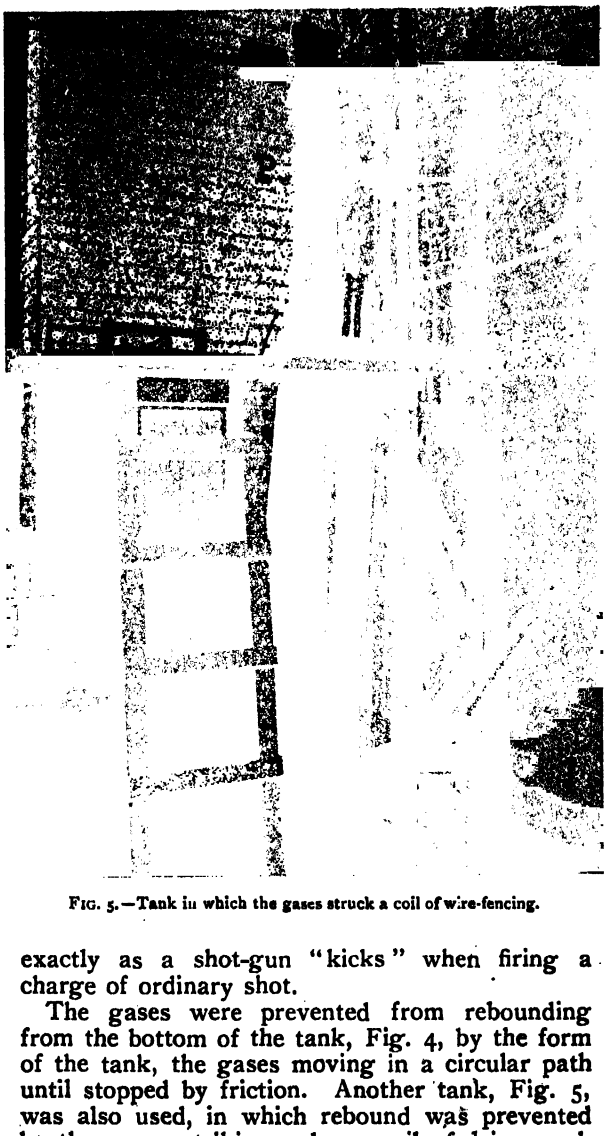

FIG. 5.—Tank in which the gases struck a coil of wire-fencing.

The gases were prevented from rebounding from the bottom of the tank, Fig. 4, by the form of the tank, the gases moving in a circular path until stopped by friction. Another tank, Fig. 5, was also used, in which rebound was prevented by the gases striking a large coil of ½-in. mesh wire-fencing. The results with both tanks agreed down to the lowest pressure employed, 0·5 mm. of mercury, which is probably the pressure that exists at a height of thirty miles.

The figures given in the Smithsonian publication regarding the initial masses necessary to propel 1 lb. to various heights, such as 12·3 lb. for 430 miles, and 438 lb. for an "infinite" altitude (for the most favourable conditions, *in so far as they are set forth in that publication*), do not assume a larger velocity of ejection of the gases than has been obtained experimentally, but do assume a greater lightness than has so far been obtained. No attempt has, however, been made to reduce any part of the apparatus to the minimum weight possible, and it is believed that with further research such lightness as is assumed is realisable.

At the present time, the work that is being done is the developing of a rocket, of small size, for employing a large number of cartridges, or charges, and this is being done on the remainder of the original grant from the Smithsonian Institution.

Application of the Method.

The most important of the immediate applications of the method is in the providing of a simple and, when sufficiently developed, inexpensive means of obtaining meteorological data at the 10-kilometre level. It is well recognised that this is the most important level for studying pressure, temperature, humidity, and wind velocity; and any means of sending recording instruments rapidly into this region, and of obtaining data soon after the ascent has been made, is certain to be of value in weather forecasting.

At greater elevations the study of temperature, pressure, wind velocity, and composition of the atmosphere is of scientific importance, and also the study of the aurora, during the day as well as at night, and the radiations from the sun that are otherwise absorbed by the atmosphere.

A further application of much general interest is the possibility of sending a mass beyond the predominating gravitational field of the earth. Concerning the possibility of demonstrating this point by hitting the moon with a rocket, it can be said, apart from the questions of aiming and of correcting the flight, that the ignition of but a few pounds of flash powder should be visible in a powerful telescope, provided, of course, that the conditions of ignition were substantially the same as those in certain experiments described in a recent Smithsonian publication, in which 1/20 of a grain fired *in vacuo* was observed at a distance of 2½ miles.

Regarding these questions, as well as others which naturally follow, the writer believes that detailed discussion, before one has checked up matters completely by experiment, is unwise, for this merely precipitates a flood of useless argument, to which reply, in some form, must be made. The ideal method, which unfortunately is not always possible, is to solve a problem completely, as was done with the tests of the jet *in vacuo*, and then to state the results.

New Aspects in the Assessment of Physical Fitness.

By DR. F. G. HOBSON, Department of Pathology, University of Oxford.

A Physician in a great city seems to be the mere plaything of Fortune; his degree of reputation is for the most part casual; they that employ him know not his excellence; they that reject him know not his deficience.—SAMUEL JOHNSON.

THESE words might, with truth, have been written of Dr. John Hutchinson, one time physician to the Brompton Hospital for Diseases of the Chest. His earlier years devoted to the study of engineering, he later turned to medicine, and carried with him into his profession that enthusiasm for the accurate expression of scientific data which must have been engendered by his early training. In 1846 he published a paper "On the Capacity of the Lungs and on the Respiratory Functions" (1)[1], in which he showed that he possessed the inspiration which is ever the mark of true genius, combined with the ability for accurate observation and the patient collection of data. He made the earliest investigations into the physiological effects of "forced breathing"; by means of a mercurial manometer he examined "expiratory force"; but interest lies for the special ends of the present subject in the extensive series of observations which he made upon the "vital capacity"[2] of more than 3000 persons covering a wide range of body size, occupation, and mode of life.

Dr. Hutchinson claimed that he had shown that "vital capacity" increases in simple arithmetical progression with increasing height, and believed that he had disproved any relationship between "vital capacity" and body weight, trunk length, or circumference of the chest. The fact that his conclusions might be open to criticism, and that the fundamental principles underlying his investigation might yet have eluded his grasp, was present in his mind, and he concluded his treatise with the following remarkable sentences, which could well be taken as a model by any scientific worker:—

> The matter of this communication is founded upon a vast number of facts—immutable truths which are infinitely beyond my comprehension. The deductions which I have ventured to draw therefrom I wish to advance with modesty, because time, with its mutations, may so unfold science as to crush these deductions and demonstrate them as unsound.
>
> Nevertheless, the facts themselves can never alter nor deviate in their bearing upon respiration, one of the most important functions of the animal economy.

This prediction has, with the passage of time, been fulfilled.

Prof. G. Dreyer, of Oxford University, has made an extensive re-investigation of the whole subject, drawing upon Hutchinson's data as well as upon his own records. In a brilliant analysis of this considerable body of observations, he has conclusively proved the existence of physiological laws which escaped the mind of the pioneer Hutchinson. On practically every point do these laws refute the conclusions reached by Hutchinson.

Prof. Dreyer (2) has shown that definite relationships do exist between "vital capacity" and body surface, body weight, trunk length, and the circumference of the chest, while no true relationship can be traced when "vital capacity" is regarded as a simple function of the standing height, as claimed by Hutchinson.

Hutchinson's misconception of the facts may be attributed in part to faulty mathematical analysis, in part to the fact that his observations were made upon subjects covering an insufficiently wide range of weight and size. It is obvious that physiological laws, if such exist, must be applicable over the entire period of growth of the individual, and must be inadequate if they can be established only over a limited range of variations of sex, age, stature, body weight, etc.

The scientific world is now familiar with the conception that certain physical, physiological, and anatomical attributes of the living organism are functions of the surface, and not of the volume, of that organism. Heat loss offers possibly the most familiar example, being relatively greater for the small body than for the large, by virtue of the relatively greater surface area presented by the small body for a given volume.

How can the surface of an animal be determined? It is simply necessary in this brief article to state that the surface can be determined indirectly from the body weight, of which it is a constant function. For justification of this procedure reference should be made to the original articles which describe the methods by which this relationship was determined (3 and 4).

Prof. Dreyer has in recent years shown that the blood volume (4), the cross-section of the aorta (5), and the cross-section of the trachea (6) are "surface functions" of the warm-blooded mammals, and not simply related to the body weight, as has often been maintained. It comes, therefore, as no surprise when he finds that "vital capacity" is also a "surface function," since this must represent, in one direction, the limit of the capacity possessed by the organism for oxygenating its blood and discharging the waste products of its metabolism, and consequently be a physiological expression of one most important aspect of respiration. It follows that this measurement gives us an index of the "vitality" of the organism, *i.e.* its ability to meet the various strains and stresses of its life.

If the "vital capacity" is a "surface function," there is the further difficulty to be faced: What

(*Continued on p.* 829.)

[1] The figures in brackets refer to the Bibliography at the end of the article.

[2] The term "vital capacity" is used to indicate the maximum amount of air the individual is able to expel from his lungs, by voluntary effort, after the deepest possible inspiration.

Oceanography and the Sea-Fisheries.*

By WILLIAM A. HERDMAN, C.B.E., D.Sc., Sc.D., LL.D., F.R.S.,

Professor of Oceanography in the University of Liverpool, President.

IT has been customary, when occasion required, for the president to offer a brief tribute to the memory of distinguished members of the Association lost to science during the preceding year. These, for the most part, have been men of advanced years and high reputation who had completed their life-work and served well in their day the Association and the sciences which it represents. Such are our late general treasurer, Prof. Perry, and our past-president, Sir Norman Lockyer, of whom the retiring president has just spoken. We have this year no other such losses to record; but it seems fitting on the present occasion to pause for a moment and devote a grateful thought to that glorious band of fine young men of high promise in science who, in the years since our Australian meeting in 1914, gave, it may be, in brief days and months of sacrifice, greater service to humanity and the advance of civilisation than would have been possible in years of normal time and work. A few names stand out already known and highly honoured—Moseley, Jenkinson, Geoffrey Smith, Keith Lucas, Gregory, and more recently Leonard Doncaster—all grievous losses; but there are also others, younger members of our Association, who had not yet had opportunity for showing accomplished work, but who equally gave up all for a great ideal. I prefer to offer a collective rather than an individual tribute. Other young men of science will arise and carry on their work, but the gap in our ranks remains. Let their successors remember that it serves as a reminder of a great example and of high endeavour worthy of our gratitude and of permanent record in the annals of science.

At the last Cardiff meeting of the British Association in 1891 you had as your president the eminent astronomer Sir William Huggins, who discoursed upon the then recent discoveries of the spectroscope in relation to the chemical nature, density, temperature, pressure, and even the motions of the stars. From the sky to the sea is a long drop, but the sciences of both have this in common: that they deal with fundamental principles and with vast numbers. More than three hundred years ago Spenser in the "Faerie Queene" compared "the seas abundant progeny" with "the starres on hy," and recent investigations show that a litre of sea-water may contain more than a hundred times as many living organisms as there are stars visible to the eye on a clear night.

During the past quarter of a century great advances have been made in the science of the sea, and the aspects and prospects of sea-fisheries research have undergone changes which encourage the hope that a combination of the work now carried on by hydrographers and biologists in most civilised countries on fundamental problems of the ocean may result in a more rational exploitation and administration of the fishing industries.

And yet even at your former Cardiff meeting thirty years ago there were at least three papers of oceanographic interest—one by Prof. Osborne Reynolds on the action of waves and currents, another by Dr. H. R. Mill on seasonal variation in the temperature of lochs and estuaries, and the third by our honorary local secretary for the present meeting, Dr. Evans Hoyle, on a deep-sea tow-net capable of being opened and closed under water by the electric current.

It was a notable meeting in several other respects, of which I shall merely mention two. In Section A Sir Oliver Lodge gave the historic address in which he expounded the urgent need, in the interests of both science and the industries, of a national institution for the promotion of physical research on a large scale. Lodge's pregnant idea put forward at this Cardiff meeting, supported and still further elaborated by Sir Douglas Galton as president of the Association at Ipswich, has since borne notable fruit in the establishment and rapid development of the National Physical Laboratory. The other outstanding event of that meeting is that you then appointed a committee of eminent geologists and naturalists to consider a project for boring through a coral reef, and that led during following years to the successive expeditions to the atoll of Funafuti, in the Central Pacific, the results of which, reported upon eventually by the Royal Society, were of great interest alike to geologists, biologists, and oceanographers.

Dr. Huggins, on taking the chair in 1891, remarked that it was more than thirty years since the Association had honoured astronomy in the selection of its president. It might be said that the case of oceanography is harder, as the Association has never had an oceanographer as president; and the Association might well reply, "Because until very recent years there has been no oceanographer to have." If astronomy is the oldest of the sciences, oceanography is probably the youngest. Depending as it does upon the methods and results of other sciences, it was not until our knowledge of physics, chemistry, and biology was relatively far advanced that it became possible to apply that knowledge to the investigation and explanation of the phenomena of the ocean. No one man has done more to apply such knowledge derived from various other subjects and to organise the results as a definite branch of science than the late Sir John Murray, who may therefore be regarded as the founder of modern oceanography.

It is to me a matter of regret that Sir John Murray was never president of the British Association. I am revealing no secret when I tell you that he might have been. On more than one occasion he was invited by the council to accept nomination, and he declined for reasons that were good and commanded our respect. He felt that the necessary duties of this post would interfere with what he regarded as his primary life-work — oceanographical explorations already planned, and the last of which he actually carried out in the North Atlantic in 1912, when above seventy years of age, in the Norwegian steamer *Michael Sars* along with his friend Dr. Johan Hjort.

Anyone considering the subject-matter of this new science must be struck by its wide range, overlapping as it does the borderlands of several other sciences and making use of their methods and facts in the solution of its problems. It is not only world-wide in its scope, but it also extends beyond our globe, and includes astronomical data in their relation to tidal and certain other oceanographical phenomena. No man in his work, or even thought, can attempt to cover the whole ground, although Sir John Murray, in his remarkably comprehensive "Summary" volumes of the *Challenger* Expedition and other writings, went far towards doing so. He, in his combination of physicist, chemist, geologist, and biologist, was the nearest approach we have had to an all-round oceanographer. The International Research Council probably acted wisely at the recent Brussels Confer-

* Presidential address delivered at the Cardiff meeting of the British Association on August 24.

ence in recommending the institution of two International Sections in our subject, one of physical and the other of biological oceanography, although the two overlap and are so interdependent that no investigator on one side can afford to neglect the other.[1]

On the present occasion I must restrict myself almost wholly to the latter division of the subject, and be content, after brief reference to the founders and pioneers of our science, to outline a few of those investigations and problems which have appeared to me to be of fundamental importance, of economic value, or of general interest.

Although the name "oceanography" was only given to this branch of science by Sir John Murray in 1880, and although, according to that veteran oceanographer Mr. J. Y. Buchanan, the last surviving member of the civilian staff of the *Challenger*, the science of oceanography was born at sea on February 15, 1873,[2] when at the first official dredging station of the expedition, to the westward of Teneriffe, at 1525 fathoms, everything that came up in the dredge was new, and led to fundamental discoveries as to the deposits forming on the floor of the ocean, still it may be claimed that the foundations of the science were laid by various explorers of the ocean at much earlier dates. Aristotle, who took all knowledge for his province, was an early oceanographer on the shores of Asia Minor. When Pytheas passed between the Pillars of Hercules into the unknown Atlantic and penetrated to British seas in the fourth century B.C., and brought back reports of Ultima Thule and of a sea to the north thick and sluggish like a jellyfish, he may have been recording an early planktonic observation. But passing over all such and many other early records of phenomena of the sea, we come to surer ground in claiming as founders of oceanography Count Marsili, an early investigator of the Mediterranean, and that truly scientific navigator Capt. James Cook, who sailed to the South Pacific on a Transit of Venus expedition in 1769, with Sir Joseph Banks as naturalist, and by afterwards circumnavigating the South Sea about latitude 60° finally disproved the existence of a great southern continent; and Sir James Clark Ross, who, with Sir Joseph Hooker as naturalist, first dredged the Antarctic in 1840.

The use of the naturalist's dredge (introduced by O. F. Müller, the Dane, in 1799) for exploring the sea-bottom was brought into prominence almost simultaneously in several countries of North-West Europe—by Henri Milne-Edwards in France in 1830, by Michael Sars in Norway in 1835, and by our own Edward Forbes about 1832.

The last-mentioned genial and many-sided genius was a notable figure in several sections of the British Association from about 1836 onwards, and may fairly be claimed as a pioneer of oceanography. In 1839 he and his friend the anatomist, John Goodsir, were dredging in the Shetland seas, with results which Forbes made known to the meeting of the British Association at Birmingham that summer, with such good effect that a "Dredging Committee"[3] of the Association was formed to continue the good work. Valuable reports on the discoveries of that committee appear in our volumes at intervals during the following twenty-five years.

It has happened over and over again in history that the British Association, by means of one of its research committees, has led the way in some important new research or development of science, and shown the Government or an industry what wants doing and how it can be done. We may fairly claim that the British Association has inspired and fostered that exploration of British seas which through marine biological investigations and deep-sea expeditions has led on to modern oceanography. Edward Forbes and the British Association Dredging Committee, Wyville Thomson, Carpenter, Gwyn Jeffreys, Norman, and other naturalists of the pre-*Challenger* days—all these men in the quarter-century from 1840 onwards worked under research committees of the British Association, bringing their results before successive meetings; and some of our older volumes enshrine classic reports on dredging by Forbes, McAndrew, Norman, Brady, Alder, and other notable naturalists of that day. These local researches paved the way for the *Challenger* and other national deep-sea expeditions. Here, as in other cases, it required private enterprise to precede and stimulate Government action.

It is probable that Forbes and his fellow-workers on this "Dredging Committee" in their marine explorations did not fully realise that they were opening up a most comprehensive and important department of knowledge. But it is also true that in all his expeditions—in the British seas from the Channel Islands to the Shetlands, in Norway, and in the Mediterranean as far as the Ægean Sea—his broad outlook on the problems of Nature was that of the modern oceanographer, and he was the spiritual ancestor of men like Sir Wyville Thomson, of the *Challenger* Expedition, and Sir John Murray, whose accidental death a few years ago, whilst still in the midst of active work, was a grievous loss to this new and rapidly advancing science of the sea.

Forbes in these marine investigations worked at border-line problems, dealing, for example, with the relations of geology to zoology and the effect of the past history of the land and sea upon the distribution of plants and animals at the present day, and in these respects he was an early oceanographer. For the essence of that new subject is that it also investigates border-line problems, and is based upon and makes use of all the older fundamental sciences—physics, chemistry, and biology—and shows, for example, how variations in the great ocean-currents may account for the movements and abundance of the migratory fishes, and how periodic changes in the physico-chemical characters of the sea, such as variations in the hydrogen-ion and hydroxyl-ion concentration, are correlated with the distribution at the different seasons of the all-important microscopic organisms that render our oceanic waters as prolific a source of food as the pastures of the land.

Another pioneer of the nineteenth century who, I sometimes think, has not yet received sufficient credit for his foresight and initiative is Sir Wyville Thomson, whose name ought to go down through the ages as the leader of the scientific staff on the famous *Challenger* Deep-Sea Exploring Expedition. It is due chiefly to him and to his friend, Dr. W. B.

[1] The following classification of the primary divisions of the subject may possibly be found acceptable:—

Physiography
- Oceanography
  - Hydrography (Physics, etc.)
  - Metabolism (Biochemistry)
  - Bionomics (Biology)
  - Tidology (Mathematics)
- Geography

[2] Others might put the date later. Significant publications are Sir John Murray's Summary Volumes of the *Challenger* (1895), the inauguration of the Musée Océanographique at Monaco in 1910, the foundation of the Institut Océanographique at Paris in 1906 (see the Prince of Monaco's letter to the Minister of Public Instruction), and Sir John Murray's little book "The Ocean" (1913), where the superiority of the term "oceanography" to "thalassography" (used by Alexander Agassiz) is discussed.

[3] "For researches with the dredge, with a view to the investigation of the marine zoology of Great Britain, the illustration of the geographical distribution of marine animals, and the more accurate determination of the fossils of the Pleistocene period: under the superintendence of Mr. Gray, Mr. Forbes, Mr. Goodsir, Mr. Patterson, Mr. Thompson of Belfast, Mr. Ball of Dublin, Dr. George Johnston, Mr. Smith of Jordan Hill, and Mr. A. Strickland, 60*l*." Report for 1839, p. xxvi.

Carpenter, that the British Government, through the influence of the Royal Society, was induced to place at the disposal of a committee of scientific experts, first the small surveying steamer *Lightning* in 1868, and then the more efficient steamer *Porcupine* in the two succeeding years, for the purpose of exploring the deep water of the Atlantic from the Faroes in the north to Gibraltar and beyond in the south, in the course of which expeditions they got successful hauls from the then unprecedented depth of 2435 fathoms, nearly three statute miles.

It will be remembered that Edward Forbes, from his observations in the Mediterranean (an abnormal sea in some respects), regarded depths of more than 300 fathoms as an azoic zone. It was the work of Wyville Thomson and his colleagues, Carpenter and Gwyn Jeffreys, on these successive dredging expeditions to prove conclusively what was beginning to be suspected by naturalists, that there is no azoic zone in the sea, but that abundant life belonging to many groups of animals extends down to the greatest depths of from four to five thousand fathoms—nearly six statute miles from the surface.

These pioneering expeditions in the *Lightning* and *Porcupine*—the results of which are not even yet fully made known to science—were epoch-making, inasmuch as they not only opened up this new region to the systematic marine biologist, but also gave glimpses of world-wide problems in connection with the physics, the chemistry, and the biology of the sea which are only now being adequately investigated by the modern oceanographer. These results, which aroused intense interest amongst the leading scientific men of the time, were so rapidly surpassed and overshadowed by the still greater achievements of the *Challenger* and other national exploring expeditions that followed in the seventies and eighties of last century, that there is some danger of their real importance being lost sight of; but it ought never to be forgotten that they first demonstrated the abundance of life of a varied nature in depths formerly supposed to be azoic, and, moreover, that some of the new deep-sea animals obtained were related to extinct forms belonging to the Jurassic, Cretaceous, and Tertiary periods.

It is interesting to recall that our Association played its part in promoting the movement that led to the *Challenger* Expedition. Our general committee at the Edinburgh meeting of 1871 recommended that the president and council be authorised to co-operate with the Royal Society in promoting "a circumnavigation expedition, specially fitted out to carry the physical and biological exploration of the deep sea into all the great oceanic areas"; and our council later appointed a committee consisting of Dr. Carpenter, Prof. Huxley, and others to co-operate with the Royal Society in carrying out these objects.

It has been said that the *Challenger* Expedition will rank in history with the voyages of Vasco da Gama, Columbus, Magellan, and Cook. Like these, it added new regions of the globe to our knowledge, and the wide expanses thus opened up for the first time, the floors of the oceans, though less accessible, are vaster than the discoveries of any previous exploration. Has not the time come for a new *Challenger* expedition?

Sir Wyville Thomson, although leader of the expedition, did not live to see the completed results, and Sir John Murray will be remembered in the history of science as the *Challenger* naturalist who brought to a successful issue the investigation of the enormous collections and the publication of the scientific results of that memorable voyage; these two Scots share the honour of having guided the destinies of what is still the greatest oceanographic exploration of all time.

In addition to taking his part in the general work of the expedition, Murray devoted special attention to three subjects of primary importance in the science of the sea, viz.: (1) The plankton or floating life of the oceans, (2) the deposits forming on the sea-bottoms, and (3) the origin and mode of formation of coral-reefs and islands. It was characteristic of his broad and synthetic outlook on Nature that, in place of working at the speciography and anatomy of some group of organisms, however novel, interesting, and attractive to the naturalist the deep-sea organisms might seem to be, he took up wide-reaching general problems with economic and geological as well as biological applications.

Each of the three main lines of investigation—deposits, plankton, and coral-reefs—which Murray undertook on board the *Challenger* has been most fruitful of results both in his own hands and in those of others. His plankton work has led on to those modern planktonic researches which are closely bound up with the scientific investigation of our sea-fisheries.

His work on the deposits accumulating on the floor of the ocean resulted, after years of study in the laboratory as well as in the field, in collaboration with the Abbé Renard, of the Brussels Museum, afterwards professor at Ghent, in the production of the monumental "Deep-Sea Deposits" volume, one of the *Challenger* reports, which first revealed to the scientific world the detailed nature and distribution of the varied submarine deposits of the globe and their relation to the rocks forming the crust of the earth.

These studies led, moreover, to one of the romances of science which deeply influenced Murray's future life and work. In accumulating material from all parts of the world and all deep-sea exploring expeditions for comparison with the *Challenger* series, some ten years later, Murray found that a sample of rock from Christmas Island, in the Indian Ocean, which had been sent to him by Comdr. (now Admiral) Aldrich, of H.M.S. *Egeria*, was composed of a valuable phosphatic material. This discovery in Murray's hands gave rise to a profitable commercial undertaking, and he was able to show that some years ago the British Treasury had already received in royalties and taxes from the island considerably more than the total cost of the *Challenger* Expedition.

That first British circumnavigating expedition on the *Challenger* was followed by other national expeditions (the American *Tuscarora* and *Albatross*, the French *Travailleur*, the German *Gauss*, *National*, and *Valdivia*, the Italian *Vettor Pisani*, the Dutch *Siboga*, the Danish *Thor*, and others) and by almost equally celebrated and important work by unofficial oceanographers such as Alexander Agassiz, Sir John Murray with Dr. Hjort in the *Michael Sars*, and the Prince of Monaco in his magnificent ocean-going yacht, and by much other good work by many investigators in smaller and humbler vessels. One of these supplementary expeditions I must refer to briefly because of its connection with sea-fisheries. The *Triton*, under Tizard and Murray in 1882, while exploring the cold and warm areas of the Faroe Channel separated by the Wyville Thomson ridge, incidentally discovered the famous Dubh-Artach fishing-grounds, which have been worked by British trawlers ever since.

Notwithstanding all this activity during the last forty years since oceanography became a science, much has still to be investigated in all seas in all branches of the subject. On pursuing any line of investigation one very soon comes up against a wall of the unknown or a maze of controversy. Peculiar difficulties surround the subject. The matters investigated are often remote and almost inaccessible. Un-

known factors may enter into every problem. The samples required may be at the other end of a rope or a wire eight to ten miles long, and the oceanographer may have to grope for them literally in the dark and under other difficult conditions which make it uncertain whether his samples when obtained are adequate and representative, and whether they have undergone any change since leaving their natural environment. It is not surprising, then, that in the progress of knowledge mistakes have been made and corrected, and that views have been held on what seemed good scientific grounds which later on were proved to be erroneous. For example, Edward Forbes, in his division of life in the sea into zones, on what then seemed to be sufficiently good observations in the Ægean, but which we now know to be exceptional, placed the limit of life at 300 fathoms, while Wyville Thomson and his fellow-workers on the *Porcupine* and the *Challenger* showed that there is no azoic zone even in the great abysses.

Or, again, take the celebrated myth of Bathybius. In the sixties of last century samples of Atlantic mud, taken when surveying the bottom for the first telegraph cables and preserved in alcohol, were found when examined by Huxley, Haeckel, and others to contain what seemed to be an exceedingly primitive protoplasmic organism, which was supposed on good evidence to be extended widely over the floor of the ocean. The discovery of this Bathybius was said to solve the problem of how the deep-sea animals were nourished in the absence of seaweeds. Here was a widespread protoplasmic meadow upon which other organisms could graze. Belief in Bathybius seemed to be confirmed and established by Wyville Thomson's results in the *Porcupine* Expedition of 1869, but was exploded by the naturalists on the *Challenger* some five years later. Buchanan in his recently published "Accounts Rendered" tells us how he and his colleague Murray were keenly on the look-out for hours at a time on all possible occasions for traces of this organism, and how they finally proved, in the spring of 1875 on the voyage between Hong-Kong and Yokohama, that the all-pervading substance like coagulated mucus was an amorphous precipitate of sulphate of lime thrown down from the sea-water in the mud on the addition of a certain proportion of alcohol. He wrote to this effect from Japan to Prof. Crum Brown, and it is in evidence that after receiving this letter Crum Brown interested his friends in Edinburgh by showing them how to make Bathybius in the chemical laboratory. Huxley at the Sheffield meeting of the British Association in 1879 handsomely admitted that he had been mistaken, and it is said that he characterised Bathybius as "not having fulfilled the promise of its youth." Will any of our present oceanographic beliefs share the fate of Bathybius in the future? Some may, but even if they do they may well have been useful steps in the progress of science. Although, like Bathybius, they may not have fulfilled the promise of their youth, yet we may add they will not have lived in the minds of man in vain.

Many of the phenomena we encounter in oceanographic investigations are so complex, are or may be affected by so many diverse factors, that it is difficult, if indeed possible, to be sure that we are unravelling them aright and see the real causes of what we observe.

Some few things we know approximately, nothing completely. We know that the greatest depths of the ocean, about six miles, are a little greater than the highest mountains on land, and Sir John Murray has calculated that if all the land were washed down into the sea the whole globe would be covered by an ocean averaging about two miles in depth.[4] We know the distribution of temperatures and salinities over a great part of the surface and a good deal of the bottom of the oceans, and some of the more important oceanic currents have been charted and their periodic variations, such as those of the Gulf Stream, are being studied. We know a good deal about the organisms floating or swimming in the surface waters (the epi-plankton), and also those brought up by our dredges and trawls from the bottom in many parts of the world, although every expedition still makes large additions to knowledge. The region that is least known to us, both in its physical conditions and in its inhabitants, is the vast zone of intermediate waters lying between the upper few hundred fathoms and the bottom. That is the region that Alexander Agassiz, from his observations with closing tow-nets on the *Blake* Expedition, supposed to be destitute of life, or at least, as modified by his later observations on the *Albatross*, to be relatively destitute compared with the surface and the bottom, in opposition to the contention of Murray and other oceanographers that an abundant meso-plankton was present, and that certain groups of animals, such as the Challengerida and some kinds of Medusæ, were characteristic of these deeper zones. I believe that, as sometimes happens in scientific controversies, both sides were right up to a point, and both could support their views upon observations from particular regions of the ocean in certain circumstances.

But much still remains unknown or only imperfectly known even in matters that have long been studied and where practical applications of great value are obtained—such as the investigation and prediction of tidal phenomena. We are now told that theories require reinvestigation, and that published tables are not sufficiently accurate. To take another practical application of oceanographic work, the ultimate causes of variations in the abundance, in the sizes, in the movements, and in the qualities of the fishes of our coastal industries are still to seek, and, notwithstanding volumes of investigation and a still greater volume of discussion, no man who knows anything of the matter is satisfied with our present knowledge of even the best-known and economically most important of our fishes such as the herring, the cod, the plaice, and the salmon.

Take the case of our common fresh-water eel as an example of how little we know and at the same time of how much has been discovered. All the eels of our streams and lakes of North-West Europe live and feed and grow under our eyes without reproducing their kind; no spawning eel has ever been seen. After living for years in immaturity, at last near the end of their lives the large male and female yellow eels undergo a change in appearance and in nature. They acquire a silvery colour and their eyes enlarge, and in this bridal attire they commence the long journey which ends in maturity, reproduction, and death. From all the fresh waters they migrate in the autumn to the coast, from the inshore seas to the open ocean and still westward and south to the mid-Atlantic, and we know not how much further, for the exact locality and manner of spawning have still to be discovered. The youngest known stages of the Leptocephalus, the larval stage of eels, have been found by the Dane, Dr. Johannes Schmidt, to the west of the Azores, where the water is more than 2000 fathoms in depth. These were about one-third of an inch in length, and were probably not long hatched. I cannot now refer to all the able inves-

[4] It was possibly in such a former world-wide ocean of ionised water that, according to the recent speculations of A. H. Church ("Thalassiophyta," 1919), the first living organisms were evolved, to become later the floating unicellular plants of the primitive plankton.

tigators—Grassi, Hjort, and others—who have discovered and traced the stages of growth of the Leptocephalus and its metamorphosis into the "elvers" or young eels which are carried by the North Atlantic drift back to the coasts of Europe and ascend our rivers in spring in countless myriads; but no man has been more indefatigable and successful in the quest than Dr. Schmidt, who in the various expeditions of the Danish investigation steamer *Thor* from 1904 onwards found successively younger and younger stages, and is during the present summer engaged in a traverse of the Atlantic to the West Indies in the hope of finding the missing link in the chain, the actual spawning fresh-water eel in the intermediate waters somewhere above the abysses of the open ocean.[5]

Again, take the case of an interesting oceanographic observation which, if established, may be found to explain the variations in time and amount of important fisheries. Otto Pettersson in 1910 discovered by his observations in the Gullmar Fjord the presence of periodic submarine waves of deeper salter water in the Kattegat and the fjords of the west coast of Sweden, which draw in with them from the Jutland banks vast shoals of the herrings which congregate there in autumn. The deeper layer consists of "bankwater" of salinity 32 to 34 per thousand, and as this rolls in along the bottom as a series of huge undulations it forces out the overlying fresher water, and so the herrings living in the "bankwater" outside are sucked into the Kattegat and neighbouring fjords and give rise to important local fisheries. Pettersson connects the crests of the submarine waves with the phases of the moon. Two great waves of salter water which reached up to the surface took place in November, 1910, one near the time of full moon and the other about new moon, and the latter was at the time when the shoals of herring appeared inshore and provided a profitable fishery. The coincidence of the oceanic phenomena with the lunar phases is not, however, very exact, and doubts have been expressed as to the connection; yet, if established, and even if found to be due, not to the moon, but to prevalent winds or the influence of ocean currents, this would be a case of the migration of fishes depending upon mechanical causes, while in other cases it is known that migrations are due to spawning needs or for the purpose of feeding, as in the case of the cod and the herring in the west and north of Norway and in the Barents Sea.

Then, turning to a very fundamental matter of purely scientific investigation, we do not know with any certainty what causes the great and all-important seasonal variations in the plankton (or floating minute life of the sea) as seen, for example, in our own home seas, where there is a sudden awakening of microscopic plant-life, the Diatoms, in early spring when the water is at its coldest. In the course of a few days the upper layers of the sea may become so filled with organisms that a small silk net towed for a few minutes may capture hundreds of millions of individuals. And these myriads of microscopic forms, after persisting for a few weeks, may disappear as suddenly as they came, to be followed by swarms of Copepoda and many other kinds of minute animals, and these again may give place in the autumn to a second maximum of Diatoms or of the closely related Peridiniales. Of course, there are theories as to all these more or less periodic changes in the plankton, such as Liebig's "law of the minimum," which limits the production of an organism by the amount of that necessity of existence which is present in least quantity, it may be nitrogen or silicon or phosphorus. According to Raben, it is the accumulation of silicic acid in the sea-water that determines the great increase of Diatoms in spring and again in autumn. Some writers have considered these variations in the plankton to be caused largely by changes in temperature supplemented, according to Ostwald, by the resulting changes in the viscosity of the water; but Murray and others are more probably correct in attributing the spring development of phyto-plankton to the increasing power of the sunlight and its value in photosynthesis.

Let us take next the fact—if it be a fact—that the genial, warm waters of the tropics support a less abundant plankton than the cold polar seas. The statement has been made and supported by some investigators and disputed by others, both on a certain amount of evidence. This is possibly a case like some other scientific controversies where both sides are partly in the right or right under certain conditions. At any rate, there are marked exceptions to the generalisation. The German Plankton Expedition in 1889 showed in its results that much larger hauls of plankton per unit-volume of water were obtained in the temperate North and South Atlantic than in the tropics between, and that the warm Sargasso Sea had a remarkably scanty microflora. Other investigators have since reported more or less similar results. Lohmann found the Mediterranean plankton to be less abundant than that of the Baltic; gatherings brought back from tropical seas are frequently very scanty, and enormous hauls, on the other hand, have been recorded from Arctic and Antarctic seas. There is no doubt about the large gatherings obtained in northern waters. I have myself in a few minutes' haul of a small horizontal net in the north of Norway collected a mass of the large Copepod, *Calanus finmarchicus*, sufficient to be cooked and eaten like potted shrimps by half a dozen of the yacht's company, and I have obtained similar large hauls in the cold Labrador current near Newfoundland. On the other hand, Kofoid and Alexander Agassiz have recorded large hauls of plankton in the Humboldt current off the west coast of America, and during the *Challenger* Expedition some of the largest quantities of plankton were found in the equatorial Pacific. Moreover, it is common knowledge that on occasions vast swarms of some planktonic organism may be seen in tropical waters. The yellow alga, Trichodesmium, which is said to have given its name to the Red Sea, and has been familiarly known as "sea-sawdust" since the days of Cook's first voyage,[6] may cover the entire surface over considerable areas of the Indian and South Atlantic Oceans; and some pelagic animals, such as Salpæ, Medusæ, and Ctenophores, are also commonly present in abundance in the tropics. Then, again, American biologists[7] have pointed out that the warm waters of the West Indies and Florida may be noted for the richness of their floating life for periods of years, while at other times the pelagic organisms become rare and the region is almost a desert sea.

It is probable, on the whole, that the distribution and variations of oceanic currents have more than latitude or temperature alone to do with any observed scantiness of tropical plankton. These mighty rivers of the ocean in places teem with animal- and plant-life, and may sweep abundance of food from one region to another in the open sea.

But even if it be a fact that there is this alleged deficiency in tropical plankton, there is by no means

[5] According to Schmidt's results, the European fresh-water eel, in order to be able to propagate, requires a depth of at least 500 fathoms, a salinity of more than 35·20 per mile, and a temperature of more than 7° C. in the required depth.

[6] See "Journal" of Sir Joseph Banks. This and other swarms were also noticed by Darwin during the voyage of the *Beagle*.

[7] A. Agassiz A. G. Mayer, and H. B. Bigelow.

agreement as to the cause thereof. Brandt first attributed the poverty of the plankton in the tropics to the destruction of nitrates in the sea as a result of the greater intensity of the metabolism of denitrifying bacteria in the warmer water; and various writers since then have more or less agreed that the presence of these denitrifying bacteria, by keeping down to a minimum the nitrogen concentration in tropical waters, may account for the relative scarcity of the phyto-plankton, and, consequently, of the zoo-plankton, that has been observed. But Gran, Nathansohn, Murray, Hjort, and others have shown that such bacteria are rare or absent in the open sea, that their action must be negligible, and that Brandt's hypothesis is untenable. It seems clear, moreover, that the plankton does not vary directly with the temperature of the water. Furthermore, Nathansohn has shown the influence of the vertical circulation in the water upon the nourishment of the phyto-plankton—by rising currents bringing up necessary nutrient materials, and especially carbon dioxide, from the bottom layers; and also possibly by conveying the products of the drainage of tropical lands to more polar seas so as to maintain the more abundant life in the colder water.

Pütter's view is that the increased metabolism in the warmer water causes all the available food materials to be used up rapidly, and so puts a check to the reproduction of the plankton.

According to van't Hoff's law in chemistry, the rate at which a reaction takes place is increased by raising the temperature, and this probably holds good for all biochemical phenomena, and therefore for the metabolism of animals and plants in the sea. This has been verified experimentally in some cases by J. Loeb. The contrast between the plankton of Arctic and Antarctic zones, consisting of large numbers of small crustaceans belonging to comparatively few species, and that of tropical waters, containing a great many more species generally of smaller size and fewer in number of individuals, is to be accounted for, according to Sir John Murray and others, by the rate of metabolism in the organisms. The assemblages captured in cold polar waters are of different ages and stages, young and adults of several generations occurring together in profusion,[8] and it is supposed that the adults "may be ten, twenty, or more years of age." At the low temperature the action of putrefactive bacteria and of enzymes is very slow or in abeyance, and the vital actions of the Crustacea take place more slowly and the individual lives are longer. On the other hand, in the warmer waters of the tropics the action of the bacteria is more rapid, metabolism in general is more active, and the various stages in the life-history are passed through more rapidly, so that the smaller organisms of equatorial seas probably live only for days or weeks in place of years.

This explanation may account also for the much greater quantity of living organisms which has been found so often on the sea-floor in polar waters. It is a curious fact that the development of the polar marine animals is, in general, "direct" without larval pelagic stages, the result being that the young settle down on the floor of the ocean in the neighbourhood of the parent forms, so that there come to be enormous congregations of the same kind of animal within a limited area, and the dredge will in a particular haul come up filled with hundreds, it may be, of an Echinoderm, a Sponge, a Crustacean, a Brachiopod, or an Ascidian; whereas in warmer seas the young pass through a pelagic stage and so become more widely distributed over the floor of the ocean. The *Challenger* Expedition found in the Antarctic certain Echinoderms, for example, which had young in various stages of development attached to some part of the body of the parents, whereas in temperate or tropical regions the same class of animals set free their eggs and the development proceeds in the open water quite independently of, and it may be far distant from, the parent.

Another characteristic result of the difference in temperature is that the secretion of carbonate of lime in the form of shells and skeletons proceeds more rapidly in warm than in cold water. The massive shells of molluscs, the vast deposits of carbonate of lime formed by corals and by calcareous seaweeds, are characteristic of the tropics; whereas in polar seas, while the animals may be large, they are for the most part soft-bodied and destitute of calcareous secretions. The calcareous pelagic Foraminifera are characteristic of tropical and sub-tropical plankton, and few, if any, are found in polar waters. Globigerina ooze, a calcareous deposit, is abundant in equatorial seas, while in the Antarctic the characteristic deposit is siliceous Diatomaceous ooze.

The part played by bacteria in the metabolism of the sea is very important and probably of wide-reaching effect, but we still know very little about it. A most promising young Cambridge biologist, the late Mr. G. Harold Drew, now unfortunately lost to science, had already done notable work at Jamaica and at Tortugas, Florida, on the effects produced by a bacillus which is found in the surface waters of these shallow tropical seas and in the mud at the bottom; and which denitrifies nitrates and nitrites, giving off free nitrogen. He found that this *Bacillus calcis* also caused the precipitation of soluble calcium salts in the form of calcium carbonate ("drewite") on a large scale in the warm shallow waters. Drew's observations tend to show that the great calcareous deposits of Florida and the Bahamas previously known as "coral muds" are not, as was supposed by Murray and others, derived from broken-up corals, shells, nullipores, etc., but are minute particles of carbonate of lime which have been precipitated by the action of these bacteria.[9]

The bearing of these observations upon the formation of oolitic limestones and the fine-grained unfossiliferous Lower Palæozoic limestones of New York State, recently studied in this connection by R. M. Field,[10] must be of peculiar interest to geologists, and forms a notable instance of the annectant character of oceanography, bringing the metabolism of living organisms in the modern sea into relation with palæozoic rocks.

The work of marine biologists on the plankton has been in the main *qualitative*, the identification of species, the observation of structure, and the tracing of life-histories. The oceanographer adds to that the *quantitative* aspect when he attempts to estimate numbers and masses per unit-volume of water or of area. Let me lay before you a few thoughts in regard to some such attempts, mainly for the purpose of showing the difficulties of the investigation. Modern quantitative methods owe their origin to the ingenious and laborious work of Victor Hensen, followed by Brandt, Apstein, Lohmann, and others of the Kiel school of quantitative planktologists. We may take their well-known estimations of fish-eggs in the North Sea as an example of the method.

The floating eggs and embryos of our more important food-fishes may occur in quantities in the plankton during certain months in spring, and Hensen and

8 Whether, however, the low temperature may not also retard reproduction is worthy of consideration.

9 Journ. Mar. Biol. Assoc., October, 1911.

10 Carnegie Institution of Washington, "Year Book for 1919," p. 197.

Apstein have made some notable calculations based on the occurrence of these in certain hauls taken at intervals across the North Sea, which led them to the conclusion that, taking six of our most abundant fish, such as the cod and some of the flat-fish, the eggs present were probably produced by about 1,200,000,000 spawners, enabling them to calculate that the total fish population of the North Sea (of these six species) at that time (the spring of 1895) amounted to about 10,000,000,000. Further calculations led them to the result that the fishermen's catch of these fishes amounted to about one-quarter of the total population. Now all this is not only of scientific interest, but also of great practical importance if we could be sure that the samples upon which the calculations are based were adequate and representative, but it will be noted that these samples represent only 1 square metre in 3,465,968,354. Hensen's statement, repeated in various works in slightly differing words, is to the effect that, using a net of which the constants are known hauled vertically through a column of water from a certain depth to the surface, he can calculate the volume of water filtered by the net and so estimate the quantity of plankton under each square metre of the surface; and his whole results depend upon the assumption, which he considers justified, that the plankton is evenly distributed over large areas of water which are under similar conditions. In these calculations in regard to the fish-eggs he takes the whole of the North Sea as being an area under similar conditions, but we have known since the days of P. T. Cleve and from the observations of Hensen's own colleagues that this is not the case, and they have published chart-diagrams showing that at least three different kinds of water under different conditions are found in the North Sea, and that at least five different planktonic areas may be encountered in making a traverse from Germany to the British Isles. If the argument be used that wherever the plankton is found to vary there the conditions cannot be uniform, then few areas of the ocean of any considerable size remain as cases suitable for population-computation from random samples. It may be doubted whether even the Sargasso Sea, which is an area of more than usually uniform character, has a sufficiently evenly distributed plankton to be treated by Hensen's method of estimation of the population.

In the German Plankton Expedition of 1889 Schütt reports that in the Sargasso Sea, with its relatively high temperature, the twenty-four catches obtained were uniformly small in quantity. His analysis of the volumes of these catches shows that the average was 3·33 c.c., but the individual catches ranged from 1·5 c.c. to 6·5 c.c., and the divergence from the average may be as great as +3·2 c.c.; and, after deducting 20 per cent. of the divergence as due to errors of the experiment, Schütt estimates the mean variation of the plankton at about 16 per cent. above or below. This does not seem to me to indicate the uniformity that might be expected in this "halistatic" area occupying the centre of the North Atlantic Gulf Stream circulation. Hensen also made almost simultaneous hauls with the same net in quick succession to test the amount of variation, and found that the average error was about 13 per cent.

As so much depends in all work at sea upon the weather, the conditions under which the ship is working, and the care taken in the experiment, with the view of getting further evidence under known conditions I carried out similar experiments at Port Erin on four occasions during last April and on a further occasion a month later, choosing favourable weather and conditions of tide and wind so as to be able to maintain an approximate position. On each of four days in April the Nansen net, with No. 20 silk, was hauled six times from the same depth (on two occasions 8 fathoms and on two occasions 20 fathoms), the hauls being taken in rapid succession and the catches emptied from the net into bottles of 5 per cent. formaline, in which they remained until examined microscopically.

The results were of interest, for although they showed considerable uniformity in the amount of the catch—for example, six successive hauls from 8 fathoms being all of them 0·2 c.c., and four out of five from 20 fathoms being 0·6 c.c.—the volume was made up rather differently in the successive hauls. The same organisms occur for the most part in each haul, and the chief groups of organisms are present in much the same proportion. For example, in a series where the Copepoda average about 100, the Dinoflagellates average about 300 and the Diatoms about 8000, but the percentage deviation of individual hauls from the average may be as much as *plus* or *minus* 50. The numbers for each organism (about 40) in each of the twenty-six hauls have been worked out, and the details will be published elsewhere, but the conclusion I come to is that if on each occasion one haul only in place of six had been taken, and if one had used that haul to estimate the abundance of any one organism in that sea-area, one might have been about 50 per cent. wrong in either direction.

Successive improvements and additions to Hensen's methods in collecting plankton have been made by Lohmann, Apstein, Gran, and others, such as pumping up water of different layers through a hose-pipe and filtering it through felt, filter-paper, and other materials which retain much of the micro-plankton that escapes through the meshes of the finest silk. Use has even been made of the extraordinarily minute and beautifully regular natural filter spun by the pelagic animal Appendicularia for the capture of its own food. This grid-like trap, when dissected out and examined under the microscope, reveals a surprising assemblage of the smallest protozoa and protophyta, less than 30 micro-millimetres in diameter, which would all pass easily through the meshes of our finest silk nets.

The latest refinement in capturing the minutest-known organisms of the plankton (excepting the bacteria) is a culture method devised by Dr. E. J. Allen, director of the Plymouth Laboratory.[11] By diluting half a cubic centimetre of the sea-water with a considerable amount (1500 c.c.) of sterilised water treated with a nutrient solution, and distributing that over a large number (70) of small flasks in which after an interval of some days the number of different kinds of organisms which had developed in each flask was counted, he calculates that the sea contains 464,000 of such organisms per litre; and he gives reasons why his cultivations must be regarded as minimum results, and states that the total per litre may well be something like a million. Thus every new method devised seems to multiply many times the probable total population of the sea. As further results of the quantitative method, it may be recorded that Brandt found about 200 Diatoms per drop of water in Kiel Bay, and Hensen estimated that there are several hundred millions of Diatoms under each square metre of the North Sea or the Baltic. It has been calculated that there is approximately one Copepod in each cubic inch of Baltic water, that the annual consumption of these Copepoda by herring is about a thousand billion, and that in the sixteen square miles of a certain Baltic fishery there is Copepod food for more than 530,000,000 herring of an average weight of 60 grams.

[11] Journ. Mar. Biol. Assoc., vol. xii., p. 1, July, 1919.

There are many other problems of the plankton in addition to quantitative estimates—probably some that we have not yet recognised—and various interesting conclusions may be drawn from recent planktonic observations. Here is a case of the introduction and rapid spread of a form new to British seas.

Biddulphia sinensis is an exotic Diatom which, according to Ostenfeld, made its appearance at the mouth of the Elbe in 1903, and spread during successive years in several directions. It appeared suddenly in our plankton gatherings at Port Erin in November, 1909, and has been present in abundance each year since. Ostenfeld in 1908, when tracing its spread in the North Sea, found that the migration to the north along the coast of Denmark to Norway corresponded with the rate of flow of the Jutland current to the Skager Rak, viz. about 17 cm. per second—a case of plankton distribution throwing light on hydrography—and he predicted that it would soon be found in the English Channel. Dr. Marie Lebour, who recently examined the store of plankton gatherings at the Plymouth Laboratory, finds that, as a matter of fact, this form did appear in abundance in the collections of October, 1909, within a month of the time when, according to our records, it reached Port Erin. Whether or not this is an Indo-Pacific species brought accidentally by a ship from the Far East, or whether it is possibly a new mutation which appeared suddenly in our seas, there is no doubt that it was not present in our Irish Sea plankton gatherings previous to 1909, but has been abundant since that year, and has completely adopted the habits of its English relations, appearing with *B. mobiliensis* in late autumn, persisting during the winter, reaching a maximum in spring, and dying out before summer.

The Nauplius and Cypris stages of Balanus in the plankton form an interesting study. The adult barnacles are present in enormous abundance on the rocks round the coast, and they reproduce in winter at the beginning of the year. The newly emitted young are sometimes so abundant as to make the water in the shore-pools and in the sea close to the shore appear muddy. The Nauplii first appeared at Port Erin in 1907 in the bay gatherings on February 22 (in 1908 on February 13), and increased with ups and downs to their maximum on April 15, and then decreased until their disappearance on April 26. None were taken at any other time of the year. The Cypris stage follows on after the Nauplius. It was first taken in the bay on April 6, rose to its maximum on the same day with the Nauplii, and was last caught on May 24. Throughout the Cypris curve keeps below that of the Nauplius, the maxima being 1740 and 10,500 respectively. Probably the difference between the two curves represents the death-rate of Balanus during the Nauplius stage. That conclusion I think we are justified in drawing, but I would not venture to use the result of any haul, or the average of a number of hauls, to multiply by the number of square yards in a zone round our coast in order to obtain an estimate of the number of young barnacles or of the old barnacles that produced them; the irregularities are too great.

To my mind it seems clear that there must be three factors making for irregularity in the distribution of a plankton organism:

(1) The sequence of stages in its life-history, such as the Nauplius and Cypris stages of Balanus.

(2) The results of interaction with other organisms, as when a swarm of Calanus is pursued and devoured by a shoal of herring.

(3) Abnormalities in time or abundance due to the physical environment, as in favourable or unfavourable seasons.

And these factors must be at work in the open ocean as well as in coastal waters.

In many oceanographical inquiries there is a double object. There is the scientific interest and there is the practical utility—the interest, for example, of tracing a particular swarm of a Copepod like Calanus, and of making out why it is where it is at a particular time, tracing it back to its place of origin, finding that it has come with a particular body of water, and perhaps that it is feeding upon a particular assemblage of Diatoms; endeavouring to give a scientific explanation of every stage in its progress. Then there is the utility—the demonstration that the migration of the Calanus has determined the presence of a shoal of herring or mackerel that are feeding upon it, and so have been brought within the range of the fisherman and have constituted a commercial fishery.

We have evidence that pelagic fish which congregate in shoals, such as herring and mackerel, feed upon the Crustacea of the plankton, and especially upon Copepoda. A few years ago when the summer herring fishery off the south end of the Isle of Man was unusually near the land, the fishermen found large red patches in the sea where the fish were specially abundant. Some of the red stuff brought ashore by the men was examined at the Port Erin Laboratory, and found to be swarms of the Copepod, *Temora longicornis*; and the stomachs of the herring caught at the same time were engorged with the same organism. It is not possible to doubt that during these weeks of the herring fishery in the Irish Sea the fish were feeding mainly upon this species of Copepod. Some ten years ago Dr. E. J. Allen and Mr. G. E. Bullen published[12] some interesting work from the Plymouth Marine Laboratory demonstrating the connection between mackerel and Copepoda and sunshine in the English Channel; and Farran[13] states that in the spring fishery on the West of Ireland the food of the mackerel is mainly composed of Calanus.

Then again, at the height of the summer mackerel fishery in the Hebrides in 1913, we found[14] the fish feeding upon the large Copepod, *Calanus finmarchicus*, which was caught in the tow-net at the rate of about 6000 in a five minutes' haul, and 6000 was also the average number found in the stomachs of the fish caught at the same time.

These were cases where the fish were feeding upon the organism that was present in swarms—a monotonic plankton—but in other cases the fish are clearly selective in their diet. If the sardine of the French coast can pick out from the micro-plankton the minute Peridiniales in preference to the equally minute Diatoms which are present in the sea at the same time, there seems no reason why the herring and the mackerel should not be able to select particular species of Copepoda or other large organisms from the macro-plankton, and we have evidence that they do. Nearly thirty years ago the late Mr. Isaac Thompson, a constant supporter of the Zoological Section of this Association and one of the honorary local secretaries for the last Liverpool meeting, showed me in 1893 that young plaice at Port Erin were selecting one particular Copepod, a species of Jonesiella, out of many others caught in our tow-nets at the time. H. Blegvad[15] showed in 1916 that young food-fishes, and also small shore-fishes, pick out certain species of Copepoda (such as Harpacticoids) and catch them individually—either lying in wait or searching for them. A couple

of years later[16] Dr. Marie Lebour published a detailed account of her work at Plymouth on the food of young fishes, proving that certain fish undoubtedly do prefer certain planktonic food.

These Crustacea of the plankton feed upon smaller and simpler organisms—the Diatoms, the Peridinians, and the Flagellates—and the fish themselves in their youngest post-larval stages are nourished by the same minute forms of the plankton. Thus it appears that our sea-fisheries ultimately depend upon the living plankton, which no doubt, in its turn, is affected by hydrographic conditions. A correlation seems to be established between the Cornish pilchard fisheries and periodic variations in the physical characters (probably the salinity) of the water of the English Channel between Plymouth and Jersey.[17] Apparently a diminished intensity in the Atlantic current corresponds with a diminished fishery in the following summer. Possibly the connection in these cases is through an organism of the plankton.

It is only a comparatively small number of different kinds of organisms—both plants and animals—that make up the bulk of the plankton that is of real importance to fish. One can select about half a dozen species of Copepoda which constitute the greater part of the summer zoo-plankton suitable as food for larval or adult fishes, and about the same number of generic types of Diatoms which similarly make up the bulk of the available spring phyto-plankton year after year. This fact gives great economic importance to the attempt to determine with as much precision as possible the times and conditions of occurrence of these dominant factors of the plankton in an average year. An obvious further extension of this investigation is an inquiry into the degree of coincidence between the times of appearance in the sea of the plankton organisms and of the young fish, and the possible effect of any marked absence of correlation in time and quantity.

Just before the war the International Council for the Exploration of the Sea[18] arrived at the conclusion that fishery investigations indicated the probability that the great periodic fluctuations in the fisheries are connected with the fish-larvæ being developed in great quantities only in certain years. Consequently they advised that plankton work should be directed primarily to the question whether these fluctuations depend upon differences in the plankton production in different years. It was then proposed to begin systematic investigation of the fish-larvæ and the plankton in spring and to determine more definitely the food of the larval fish at various stages.

About the same time Dr. Hjort[19] made the interesting suggestion that possibly the great fluctuations in the number of young fish observed from year to year may not depend wholly upon the number of eggs produced, but also upon the relation in time between the hatching of these eggs and the appearance in the water of the enormous quantity of Diatoms and other plant plankton upon which the larval fish, after the absorption of their yolk, depend for food. He points out that if even a brief interval occurs between the time when the larvæ first require extraneous nourishment and that when such food is available, it is highly probable that an enormous mortality would result. In that case even a rich spawning season might yield but a poor result in fish in the commercial fisheries of successive years for some time to come. So that, in fact, the numbers of a year-class may depend not so much upon a favourable spawning season as upon a coincidence between the hatching of the larvæ and the presence of abundance of phyto-plankton available as food.[20]

The curve for the spring maximum of Diatoms corresponds in a general way with the curve representing the occurrence of pelagic fish-eggs in our seas. But is the correspondence sufficiently exact and constant to meet the needs of the case? The phyto-plankton may still be relatively small in amount during February and part of March in some years, and it is not easy to determine exactly when, in the open sea, the fish-eggs have hatched out in quantity and the larvæ have absorbed their food-yolk and started feeding on Diatoms.

If, however, we take the case of one important fish—the plaice—we can get some data from our hatching experiments at the Port Erin Biological Station, which have now been carried on for a period of seventeen years. An examination of the hatchery records for these years in comparison with the plankton records of the neighbouring sea, which have been kept systematically for the fourteen years from 1907 to 1920 inclusive, shows that in most of these years the Diatoms were present in abundance in the sea a few days at least before the fish-larvæ from the hatchery were set free, and that it was only in four years (1908, 1909, 1913, and 1914) that there was apparently some risk of the larvæ finding no phyto-plankton food or very little. The evidence so far seems to show that if fish-larvæ are set free in the sea so late as March 20 they are fairly sure of finding suitable food[21]; but if they are hatched so early as February they run some chance of being starved.

But this does not exhaust the risks to the future fishery. C. G. Joh. Petersen and Boysen-Jensen in their valuation of the Limfjord[22] have shown that in the case not only of some fish, but also of the larger invertebrates on which they feed, there are marked fluctuations in the number of young produced in different seasons, and that it is only at intervals of years that a really large stock of young is added to the population.

The prospects of a year's fishery may, therefore, depend primarily upon the rate of spawning of the fish, affected, no doubt, by hydrographic and other environmental conditions; secondarily, upon the presence of a sufficient supply of phyto-plankton in the surface-layers of the sea at the time when the fish-larvæ are hatched, and that, in its turn, depends upon photosynthesis and physico-chemical changes in the water; and, finally, upon the reproduction of the stock of molluscs or worms at the bottom which constitute the fish-food at later stages of growth and development.

The question has been raised in recent years: Is there enough plankton in the sea to provide sufficient nourishment for the larger animals, and especially for those fixed forms, such as sponges, that are supposed to feed by drawing currents of plankton-laden water through the body? In a series of remarkable papers from 1907 onwards Pütter and his followers put forward the views: (1) that the carbon requirements of such animals could not be met by the amount of plankton in the volume of water that could be passed through the body in a given time, and (2) that sea-water contained a large amount of dissolved organic carbon compounds which constitute the chief, if not the only, food of a large number of marine animals. These views have given rise to

20 For the purpose of this argument we may include in "phyto-plankton" the various groups of Flagellata and other minute organisms which may be present with the Diatoms.

21 All dates and statements as to occurrence refer to the Irish Sea round the south end of the Isle of Man. For further details see Report Lancs Sea-Fish. Lab. for 1919.

22 Report of Danish Biol. Station for 1919.

much controversy, and have been useful in stimulating further research, but I believe it is now admitted that Pütter's samples of water from the Bay of Naples and at Kiel were probably polluted, that his figures were erroneous, and that his conclusions must be rejected, or at least greatly modified. His estimates of the plankton were minimum ones, while it seems probable that his figures for the organic carbon present represent a variable amount of organic matter arising from one of the reagents used in the analyses.[23] The later experimental work of Henze, of Raben, and of Moore shows that the organic carbon dissolved in sea-water is an exceedingly minute quantity, well within the limits of experimental error. Moore puts it at the most at one-millionth part, or 1 mgm. in a litre At the Dundee meeting of the Association in 1912 a discussion on this subject took place, at which Pütter still adhered to a modified form of his hypothesis of the inadequacy of the plankton and the nutrition of lower marine animals by the direct absorption of dissolved organic matter. Further work at Port Erin since has shown that, while the plankton supply as found generally distributed would prove sufficient for the nutrition of such sedentary animals as Sponges and Ascidians, which require to filter only about fifteen times their own volume of water per hour, it is quite inadequate for active animals such as crustaceans and fishes. These latter are, however, able to seek out and capture their food, and are not dependent on what they may filter or absorb from the sea-water. This result accords well with recorded observations on the irregularity in the distribution of the plankton and with the variations in the occurrence of the migratory fishes which may be regarded as following and feeding upon the swarms of planktonic organisms.

This, then, like most of the subjects I am dealing with, is still a matter of controversy, still not completely understood. Our need, then, is research, more research, and *still more research.*

Our knowledge of the relations between plankton productivity and variation and the physico-chemical environment is still in its infancy, but gives promise of great results in the hands of the biochemist and the physical chemist.

Recent papers by Sørensen, Palitzsch, Witting, Moore, and others have made clear that the amount of hydrogen-ion concentration as indicated by the relative degree of alkalinity and acidity in the sea-water may undergo local and periodic variations, and that these have an effect upon the living organisms in the water and can be correlated with their presence and abundance. To take an example from our own seas, Prof. Benjamin Moore and his assistants in their work at the Port Erin Biological Station in successive years from 1912 onwards have shown[24] that the sea around the Isle of Man is a good deal more alkaline in spring (say April) than it is in summer (say July). The alkalinity, which gets low in summer, increases somewhat in autumn, and then decreases rapidly, to disappear during the winter; and then once more, after several months of a minimum, begins to come into evidence again in March, and rapidly rises to its maximum in April or May. This periodic change in alkalinity will be seen to correspond roughly with the changes in the living microscopic contents of the sea represented by the phyto-plankton annual curve, and the connection between the two will be seen when we realise that the alkalinity of the sea is due to the relative absence of carbon dioxide. In early spring, then, the developing myriads of Diatoms in their metabolic processes gradually use up the store of carbon dioxide accumulated during the winter or derived from the bicarbonates of calcium and magnesium, and so increase the alkalinity of the water until the maximum of alkalinity, due to the fixation of the carbon and the reduction in amount of carbon dioxide, corresponds with the crest of the phyto-plankton curve in, say, April. Moore has calculated that the annual turnover in the form of carbon which is used up or converted from the inorganic into an organic form probably amounts to something of the order of 20,000–30,000 tons of carbon per cubic mile of sea-water, or, say, over an area of the Irish Sea measuring 16 square miles and a depth of 50 fathoms; and this probably means a production each season of about two tons of dry organic matter, corresponding to at least ten tons of moist vegetation, per acre—which suggests that we may still be very far from getting from our seas anything like the amount of possible food-matters that are produced annually.

Testing the alkalinity of the sea-water may therefore be said merely to be ascertaining and measuring the results of the photosynthetic activity of the great phyto-plankton rise in spring due to the daily increase of sunlight.

The marine biologists of the Carnegie Institution, Washington, have made a recent contribution to the subject in certain observations on the alkalinity of the sea (as determined by hydrogen-ion concentration), during which they found in tropical mid-Pacific a sudden change to acidity in a current running eastwards. Now in the Atlantic the Gulf Stream and tropical Atlantic waters generally are much more alkaline than the colder coastal water running south from the Gulf of St. Lawrence—that is, the colder Arctic water has more carbon dioxide. This suggests that the Pacific easterly set may be due to deeper water, containing more carbon dioxide (=acidity), coming to the surface at that point. The alkalinity of the sea-water can be determined rapidly by mixing the sample with a few drops of an indicator and observing the change in colour; and this method of detecting ocean currents by observing the hydrogen-ion concentration of the water might be useful to navigators as showing the time of entrance to a known current.

Oceanography has many practical applications, chiefly, but by no means wholly, on the biological side. The great fishing industries of the world deal with living organisms, of which all the vital activities and the inter-relations with the environment are matters of scientific investigation. Aquiculture is as susceptible of scientific treatment as agriculture can be; and the fisherman, who has been in the past too much the nomad and the hunter—if not, indeed, the devastating raider—must become in the future the settled farmer of the sea if his harvest is to be less precarious. Perhaps the nearest approach to cultivation of a marine product, and of the fisherman reaping what he has actually sown, is seen in the case of the oyster and mussel industries on the west coast of France, in Holland, America, and, to a less extent, on our own coast. Much has been done by scientific men for these and other similar coastal fisheries since the days when Prof. Coste in France in 1859 introduced oysters from the Scottish oyster-beds to start the great industry at Arcachon and elsewhere. Now we buy back the descendants of our own oysters from the French ostreiculturists to replenish our depleted beds.

It is no small matter to have introduced a new and important food-fish to the markets of the world. The remarkable deep-water "tile-fish," new to science and

[23] See Moore, etc., *Bio-Chem. Journ.*, vol. vi., p. 266, 1912.

[24] "Photosynthetic Phenomena in Sea-water," Trans. Liverpool Biol. Soc., vol. xxix., p. 233, 1915.

described as *Lopholatilus chamaeleonticeps*, was discovered in 1879 by one of the United States fishing schooners to the south of Nantucket, near the 100-fathom line. Several thousand pounds' weight was caught, and the matter was duly investigated by the United States Fish Commission. For a couple of years after that the fish was brought to market in quantity, and then something unusual happened at the bottom of the sea, and in 1882 millions of dead tile-fish were found floating on the surface over an area of thousands of square miles. The schooner *Navarino* sailed for two days and a night through at least 150 miles of sea thickly covered, so far as the eye could reach, with dead fish, estimated at 256,000 to the square mile. The Fish Commission sent a vessel to fish systematically over the grounds known as the "Gulf Stream slope," where the tile-fish had been so abundant during the two previous years, but she did not catch a single fish, and the associated subtropical invertebrate fauna was also practically obliterated.

This wholesale destruction was attributed by the American oceanographers to a sudden change in the temperature of the water at the bottom, due in all probability to a withdrawal southwards of the warm Gulf Stream water and a flooding of the area by the cold Labrador current.

I am indebted to Dr. C. H. Townsend, director of the celebrated New York Aquarium, for the latest information in regard to the reappearance in quantity of this valuable fish upon the old fishing-grounds of Nantucket and Long Island, at about 100 miles from the coast to the east and south-east of New York. It is believed that the tile-fish is now abundant enough to maintain an important fishery, which will add an excellent food-fish to the markets of the United States. It is easily caught with lines at all seasons of the year, and reaches a length of more than 3 ft. and a weight of 40-50 lb. During July, 1915, the product of the fishery was about 2,500,000 lb. weight, valued at 55,000 dollars, and in the first few months of 1917 the catch was 4,500,000 lb., for which the fishermen received 247,000 dollars.

We can scarcely hope in European seas to add new food-fishes to our markets, but much may be done through the co-operation of scientific investigators of the ocean with the administrative departments to bring about a more rational conservation and exploitation of the national fisheries.

Earlier in this address I referred to the pioneer work of the distinguished Manx naturalist, Prof. Edward Forbes. There are many of his writings and of his lectures to which I have no space to refer which have points of oceanographic interest. Take this, for example, in reference to our national sea-fisheries. We find him in 1847 writing to a friend: "On Friday night I lectured at the Royal Institution. The subject was the bearing of submarine researches and distribution matters on the fishery question. I pitched into Government mismanagement pretty strong, and made a fair case of it. It seems to me that at a time when half the country is starving we are utterly neglecting or grossly mismanaging great sources of wealth and food. . . . Were I a rich man I would make the subject a hobby for the good of the country and for the better proving that the true interests of Government are those linked with and inseparable from Science." We must still cordially approve of these last words, while recognising that our Government Department of Fisheries is now being organised on better lines, is itself carrying on scientific work of national importance, and is, I am happy to think, in complete sympathy with the work of independent scientific investigators of the sea and desirous of closer co-operation with university laboratories and biological stations.

During recent years one of the most important and most frequently discussed of applications of fisheries investigation has been the productivity of the trawling grounds, and especially those of the North Sea. It has been generally agreed that the enormous increase of fishing power during the last forty years or so has reduced the number of large plaice, so that the average size of that fish caught in our home waters has become smaller, although the total number of plaice landed had continued to increase up to the year of the outbreak of war. Since then, from 1914 to 1919, there has of necessity been what may be described as the most gigantic experiment ever seen in the closing of extensive fishing-grounds. It is still too early to say with any certainty exactly what the results of that experiment have been, although some indications of an increase of the fish population in certain areas have been recorded. For example, the Danes, A. C. Johansen and Kirstine Smith, find that large plaice landed in Denmark are now more abundant, and they attribute this to a reversal of the pre-war tendency, due to less intensive fishing. But Dr. James Johnstone has pointed out that there is some evidence of a natural periodicity in abundance of such fish, and that the results noticed may represent phases in a cyclic change. If the periodicity noted in Liverpool Bay[25] holds good for other grounds, it will be necessary in any comparison of pre-war and post-war statistics to take this natural variation in abundance into very careful consideration.

In the application of oceanographic investigations to sea-fisheries problems one ultimate aim, whether frankly admitted or not, must be to obtain some kind of a rough approximation to a census or valuation of the sea—of the fishes that form the food of man, of the lower animals of the sea-bottom on which many of the fishes feed, and of the planktonic contents of the upper waters which form the ultimate organised food of the sea—and many attempts have been made in different ways to attain the desired end.

Our knowledge of the number of animals living in different regions of the sea is for the most part relative only. We know that one haul of the dredge is larger than another, or that one locality seems richer than another, but we have very little information as to the actual numbers of any kind of animal per square foot or per acre in the sea. Hensen, as we have seen, attempted to estimate the number of food-fishes in the North Sea from the number of their eggs caught in a comparatively small series of hauls of the tow-net, but the data were probably quite insufficient and the conclusions may be erroneous. It is an interesting speculation to which we cannot attach any economic importance. Heincke says of it: "This method appears theoretically feasible, but presents in practice so many serious difficulties that no positive results of real value have as yet been obtained."

All biologists must agree that to determine even approximately the number of individuals of any particular species living in a known area is a contribution to knowledge which may be of great economic value in the case of the edible fishes, but it may be doubted whether Hensen's methods, even with greatly increased data, will ever give us the required information. Petersen's method, of setting free marked plaice and then assuming that the proportion of these recaught is to the total number marked as the fishermen's catch in the same district is to the total population, will hold good only in circumscribed areas where there is practically no migration and the fish

[25] See Johnstone, Report Lancs Sea-Fish. Lab. for 1917, p. 60; and Daniel, Report for 1919, p. 51.

are fairly evenly distributed. This method gives us what has been called "the fishing coefficient," and this has been estimated for the North Sea to have a probable value of about 0·33 for those sizes of fish which are caught by the trawl. Heincke,[26] from an actual examination of samples of the stock on the ground obtained by experimental trawling ("the catch coefficient"), supplemented by the market returns of the various countries, estimates the adult plaice at about 1,500,000,000, of which about 500,000,000 are caught or destroyed by the fishermen annually.

It is difficult to imagine any further method which will enable us to estimate any such case as, say, the number of plaice in the North Sea, where the individuals are so far beyond our direct observation and are liable to change their positions at any moment. But a beginning can be made on more accessible ground with more sedentary animals, and Dr. C. G. Joh. Petersen, of the Danish Biological Station, has for some years been pursuing the subject in a series of interesting reports on "The Evaluation of the Sea."[27] He uses a bottom-sampler or grab, which can be lowered down open and then closed on the bottom so as to bring up a sample square foot or square metre (or in deep water one-tenth of a square metre) of the sand or mud and its inhabitants. With this apparatus, modified in size and weight for different depths and bottoms, Petersen and his fellow-workers have made a very thorough examination of the Danish waters, and especially of the Kattegat and the Limfjord, have described a series of "animal communities" characteristic of different zones and regions of shallow water, and have arrived at certain numerical results as to the quantity of animals in the Kattegat expressed in tons—such as 5000 tons of plaice requiring as food 50,000 tons of "useful animals" (mollusca and polychæt worms), and 25,000 tons of starfish using up 200,000 tons of useful animals which might otherwise serve as food for fishes, and the dependence of all these animals directly or indirectly upon the great Beds of Zostera, which make up 24,000,000 tons in the Kattegat. Such estimates are obviously of great biological interest, and, even if only rough approximations, are a valuable contribution to our understanding of the metabolism of the sea and of the possibility of increasing the yield of local fisheries.

But on studying these Danish results in the light of what we know of our own marine fauna, although none of our seas have been examined in the same detail by the bottom-sampler method, it seems probable that the animal communities as defined by Petersen are not exactly applicable on our coasts, and that the estimates of relative and absolute abundance may be very different in different seas under different conditions. The work will have to be done in each great area, such as the North Sea, the English Channel, and the Irish Sea, independently. This is a necessary investigation, both biological and physical, which lies before the oceanographers of the future, upon the results of which the future preservation and further cultivation of our national sea-fisheries may depend.

It has been shown by Johnstone and others that the common edible animals of the shore may exist in such abundance that an area of the sea may be more productive of food for man than a similar area of pasture or crops on land. A Lancashire mussel-bed has been shown to have as many as 16,000 young mussels per square foot, and it is estimated that in the shallow waters of Liverpool Bay there are from 20 to 200 animals of sizes varying from an amphipod to a plaice on each square metre of the bottom.[28]

From these and similar data which can be readily obtained it is not difficult to calculate totals by estimating the number of square yards in areas of similar character between tide-marks or in shallow water. And from weighings of samples some approximation to the number of tons of available food may be computed. But one must not go too far. Let all the figures be based upon actual observation. Imagination is necessary in science, but in calculating a population of even a very limited area it is best to believe only what one can see and measure.

Countings and weighings, however, do not give us all the information we need. It is something to know even approximately the number of millions of animals on a mile of shore and the number of millions of tons of possible food in a sea area, but that is not sufficient. All food-fishes are not equally nourishing to man, and all plankton and bottom invertebrata are not equally nourishing to a fish. At this point the biologist requires the assistance of the physiologist and the biochemist. We want to know next the value of our food-matters in proteids, carbohydrates, and fats, and the resulting Calories. Dr. Johnstone, of the oceanography department of the University of Liverpool, has already shown us how markedly a fat summer herring differs in essential constitution from the ordinary white fish, such as the cod, which is almost destitute of fat.

Prof. Brandt at Kiel, Prof. Benjamin Moore at Port Erin, and others have similarly shown that plankton gatherings may vary greatly in their nutrient value according as they are composed mainly of Diatoms, of Dinoflagellates, or of Copepoda. And, no doubt, the animals of the "benthos," the common invertebrates of our shores, will show similar differences in analysis.[29] It is obvious that some contain more solid flesh, others more water in their tissues, others more calcareous matter in the exoskeleton, and that therefore, weight for weight, we may be sure that some are more nutritious than others; and this is probably at least one cause of that preference we see in some of our bottom-feeding fish for certain kinds of food, such as polychæt worms, in which there is relatively little waste, and thin-shelled lamellibranch molluscs, such as young mussels, which have a highly nutrient body in a comparatively thin and brittle shell.

My object in referring to these still incomplete investigations is to direct attention to what seems a natural and useful extension of faunistic work for the purpose of obtaining some approximation to a quantitative estimate of the more important animals of our shores and shallow water and their relative values as either the immediate or the ultimate food of marketable fishes.

Each such fish has its "food-chain" or series of alternative chains, leading back from the food of man to the invertebrates upon which it preys, and then to the food of these, and so down to the smallest and simplest organisms in the sea, and each such chain must have all its links fully worked out as to seasonal and quantitative occurrence back to the Diatoms and Flagellates, which depend upon physical conditions, and take us beyond the range of biology, but not beyond that of oceanography. The Diatoms and the Flagellates are probably more important than the more obvious seaweeds not only as food, but also in

[29] Moore and others have made analyses of the protein, fat, etc., in the soft parts of Sponge, Ascidian, Aplysia, Fusus, Echinus, and Cancer at Port Erin, and find considerable differences—the protein ranging, for example, from 8 to 51 per cent., and the fat from 2 to 14 per cent. (see *Bio-Chemical Journ.*, vol. vi., p. 291).

supplying to the water the oxygen necessary for the respiration of living protoplasm. Our object must be to estimate the rate of production and rate of destruction of all organic substances in the sea.

To attain to an approximate census and valuation of the sea—remote though it may seem—is a great aim, but it is not sufficient. We want not only to observe and to count natural objects, but also to understand them. We require to know not merely what an organism is—in the fullest detail of structure and development and affinities—where it occurs—again in full detail—and in what abundance in different circumstances, but also *how* it lives and what all its relations are to both its physical and its biological environment, and that is where the physiologist, and especially the biochemist, can help us. In the best interests of biological progress the day of the naturalist who merely collects, the day of the anatomist and histologist who merely describe, is over, and the future is with the observer and the experimenter animated by a divine curiosity to enter into the life of the organism and understand how it lives and moves and has its being. "Happy indeed is he who has been able to discover the causes of things."

Cardiff is a seaport, and a great seaport, and the Bristol Channel is a notable sea-fisheries centre of growing importance. The explorers and merchant venturers of the south-west of England are celebrated in history. What are you doing now in Cardiff to advance our knowledge of the ocean? You have here an important university centre and a great modern national museum, and either or both of these homes of research might do well to establish an oceanographical department, which would be an added glory to your city and of practical utility to the country. This is the obvious centre in Wales for a sea-fisheries institute for both research and education. Many important local movements have arisen from British Association meetings, and if such a notable scientific development were to result from the Cardiff meeting of 1920, all who value the advance of knowledge and the application of knowledge to industry would applaud your enlightened action.

In a wider sense, it is not to the people of Cardiff alone that I appeal, but to the whole population of these islands, a maritime people who owe everything to the sea. I urge them to become better informed in regard to our national sea-fisheries and to take a more enlightened interest in the basal principles that underlie a rational regulation and exploitation of these important industries. National efficiency depends to a very great extent upon the degree in which scientific results and methods are appreciated by the people and scientific investigation is promoted by the Government and other administrative authorities. The principles and discoveries of science apply to aquiculture no less than to agriculture. To increase the harvest of the sea the fisheries must be continuously investigated, and such cultivation as is possible must be applied, and all this is clearly a natural application of the biological and hydrographical work now united under the science of oceanography.

Summaries of Addresses of Presidents of Sections of the British Association.

Mathematical and Physical Science.

PROF. EDDINGTON's presidential address to Section A deals with the investigation of the internal conditions of the stars. Most of the naked-eye stars have densities so low that they may be treated as spheres of perfect gas (giant stars). In familiar hot bodies the energy existing in the æther (radiant heat) is extremely small compared with that associated with the matter (molecular motions); conditions might exist in which this disproportion was reversed; but the stars are of just such a mass that the two kinds of energy are roughly equal. It is thought that this balance cannot be a coincidence, but determines why the masses of the stars are always close to a particular value. From astronomical data as to the masses and radiation of the stars it is possible to determine the opacity of stellar material to the radiation traversing it. The opacity turns out to be very high and of the same order of magnitude as that found for X-rays in the laboratory. (At the high temperatures in the stars the radiation consists mainly of soft X-rays.) A rather surprising result is that the opacity varies very little with the temperature of the star or wave-length of the radiation. The discussion leads to many astronomical results which appear to be generally confirmed by observation; in particular, it fixes within fairly narrow limits the period of a mechanical pulsation of any star, and this agrees in all known Cepheid variables with the observed period of light-pulsation. The question of the source of a star's heat is raised in an acute form by these investigations. It appears that the energy of gravitational contraction is quite inadequate. The recent experimental results of Aston and Rutherford seem to throw some new light on the often-discussed question whether sub-atomic energy can be made available in the stars. The address concludes with some observations on the legitimate place of speculation in scientific research.

Chemistry.

MR. C. T. Heycock deals in his presidential address to Section B with the manner in which our present rather detailed knowledge of metallic alloys has been acquired, starting from the sparse information which was available thirty or forty years ago, and sketches briefly the present position of the subject. He considers chiefly the non-ferrous alloys, not because any essential difference in type exists between these and ferrous alloys, but because the whole field presented by the chemistry of the metals and their alloys is too vast to be covered in an address of reasonable length. Though Réaumur in 1722 employed the microscope to examine the fractured surfaces of white and grey cast-iron and steel, and Widmanstatten in 1808 polished and etched sections from meteorites, the founder of modern metallography is undoubtedly H. C. Sorby, whose methods of polishing and etching alloys and of vertical illumination are used to-day by all who work at this subject. The first important clue to what occurs on cooling a fused mixture of metals was given by Guthrie's experiments on cryohydrates, and these researches, with those of Sorby, undertaken as they were for the sake of investigating natural phenomena, are remarkable examples of how purely scientific experiment can lead to most important practical results. Raoult's work on the depression of the freezing point of solvents due to the addition of dissolved substances led to the establishment by van't Hoff of a general theory applicable to all solutions. Later experiments established the similarity between the behaviour of metallic solutions or alloys and that of aqueous and other solutions of organic compounds in organic solvents; and in 1897 Neville and Heycock determined the complete freezing-point curve of the copper-tin alloys, confirming and extending the work of Roberts-Austen, Stansfield, and Le Chatelier. These were probably the first of the binary alloys, on

which an attempt was made to determine the changes which take place in passing from one pure constituent to the other; and without a working theory of solution the interpretation of the results would have been impossible. Many difficulties are encountered in the examination of binary alloys, but they are enormously increased in the investigation of ternary alloys, and with quaternary alloys they seem almost insurmountable; in the case of steels containing always six, and usually more, constituents, information can be obtained at present by purely empirical methods only.

Geology.

In discussing the relations of palæontology to other branches of biology in his presidential address to Section C, Dr. F. A. Bather emphasises the influence of the time-concept, which gives palæontology a fourth dimension and necessitates a new method of classification. The known facts of succession, while upsetting some rash speculations, do not, unaided, prove descent. Recapitulation, however, does furnish the desired proof. The "line-upon-line" method of research is the only sure one, and this has brought out a continuous transition in development, and definite directions leading to a seriation of forms. But this appearance of seriation, though it may be sometimes due to determinate variation, in no way implies determination; and still less do the facts warrant the belief in predetermination so generally held by palæontologists. After rebutting the various arguments for predestination, counter-adaptive degeneration, and momentum in evolution, Dr. Bather shows how light is thrown on the supposed instances by the study of adaptive form and of habitat. The varying rate of evolution, the recurrent cycles of structure, and the birth and death of races, all are dependent on the secular changes of environment. To correlate the succession of living forms with those changes is the task of the palæontologist. When completed, our geological systems will express truly the rhythm of evolution. But if there is no inevitable law of progress for any living creature, neither is there a law of decadence; and man, by controlling his environment and adapting his race through conscious selection, has but to aim at a high mark in order to prolong and hasten his ascent.

Zoology.

Prof. Stanley Gardiner in his presidential address to Section D asks the consideration of the public to the claims of zoology to support, and of the professional students of the science to the comparative sterility of much of their teaching and research. The chief claim of zoology lies in its broad applicability to human life. Harvey's researches on circulation and embryology apply directly to medicine and human growth. Malaria, typhus, dysentery, trench fever, and now, perhaps, cancer, are understandable only by the studies of the pure zoologist on insects and on the physiology of unicellular organisms. Mendel's work gives hopes of the understanding of the laws governing human heredity and of establishing immunity to many diseases. Economic entomology is founded on the seventeenth-century study of insect life-histories, and now we struggle for knowledge of the enemies or parasites of insects wherewith to destroy them by natural means. Curiosity as to the possibilities of life in the deep sea led to the opening up of great banks, without which our fishing industry would still be a small thing. River-eels migrate thousands of miles to breed, and mackerel migrations are correlated with sunlight; the Swedish herring fisheries depend on cycles of sun-spots and longer cycles of lunar changes.

Great as are such results, they approach the limit of what can be attained from the old zoological studies of anatomy, distribution and development. The future lies in the study of the living protoplasm, its universal association with water, the effects of acidity or alkalinity on reproduction and growth, the possibilities of dissolved food substances and perhaps of vitamines in water, and, finally, reproduction without the help of the male. Yet zoology is in danger, for its results are seldom immediately applicable to industry, and economic specialists are trying to make their students study their specialities without having a sufficiently broad scientific education to be able to consider what life really is. The old naturalists were largely cataloguers, but what they sought was the understanding of life. Then came in succession the anatomists, the embryologists, and the evolutionists, the last clearly seen to-day in that the subject as taught in many schools is merely history. Zoology must emancipate itself from its dry bones, and recognise that its museums and institutions are means only for the study of life itself.

Geography.

In his presidential address to Section E Mr. J. McFarlane discusses the principles upon which the territorial rearrangement of Europe has been based. He considers that the promise of stability is greatest in those cases where geographical and ethnical conditions are most in harmony, and least where undue weight has been given to considerations which are neither geographical nor ethnical. The transfer of Alsace-Lorraine to France must be defended, if at all, on the ground that its inhabitants are more attached to France than to Germany. The loss of territory which Germany has sustained both in the east and in the west is aggravated by the fact that from the regions lost she has in the past obtained much of her coal and iron-ore. Serious as her position is, however, her economic stability is not necessarily threatened. The position of Poland is geographically weak, partly because the surface features are such that the land has no well-marked individuality, and partly because there are no natural boundaries to prevent invasion or to restrain the Poles from wandering beyond the ethnic limits of their State. On the other hand, the population is sufficiently large and the Polish element within it sufficiently strong to justify its independence on ethnical grounds.

Czecho-Slovakia, in various ways the most interesting country in the reconstructed Europe, is alike geographically and ethnically marked by some features of great strength and by others of great weakness. Bohemia possesses geographical individuality, and Slovakia is at least strategically strong, but Czecho-Slovakia as a whole does not possess geographical unity, and is, in a sense, strategically weak, since Moravia, which unites Bohemia and Slovakia, lies across the great route from the Adriatic to the plains of Northern Europe. Rumania has sacrificed unity of political outlook and ethnic homogeneity by the annexation of Transylvania, while her position on the Hungarian plain is likely sooner or later to involve her in further trouble with the Magyars. Indeed, the treatment of the Hungarian plain is the most unsatisfactory part of the whole Peace settlement. In that great natural region the Magyar element is the strongest, and to divide it as has been done is to induce a position of unstable equilibrium which is likely to lead to trouble in the future.

The troubles of Austria are due to the fact that she has failed to realise that an empire such as hers can be permanently retained only on a basis of common

political and economic interest. At present she has no place in the reconstructed Europe, and a complete political re-orientation will be necessary if she is to emerge successfully from her present trials.

The pre-war frontier of Italy in the east is unsatisfactory, because it assigns to Austria the essentially Italian region of the Lower Isonzo. But beyond that region and a position on the neighbouring highlands for strategic purposes, Italy has no claim except what she can establish on ethnic grounds. The so-called "Wilson line" meets her requirements fairly well.

Economic Science and Statistics.

Dr. J. H. Clapham's presidential address to Section F contains a comparison and contrast between the economic condition of Western Europe after the Napoleonic wars and its economic condition to-day. Figures for the total losses of France and for the debt accumulated by Great Britain during the former period go to prove that if warfare in those days lacked intensity, it made up in duration. As in 1918, France was short of men, and her means of communication had suffered; her rapid recovery illustrates the essential difference between the two periods: a hundred years ago few men were demobilised in either France or Germany, and these were readily absorbed in an agricultural community. In 1816 the harvest was bad, and Western Europe approached starvation; the situation was saved only by the excellent harvest of the following year. Economic organisation was primitive, but elastic. A modern parallel is Serbia, which has improved wonderfully since the bountiful harvest of 1919. Germany suffered rather longer owing to the lack of a strong central Government; the States which have risen from the wreckage of the Austro-Hungarian Empire are now in a similar plight. Great Britain was partly industrial, and recovery was delayed by mismanagement of supplies, taxation, and demobilisation. Stocks of Colonial goods had accumulated with which home markets were flooded, and a commercial and industrial crisis followed. A similar situation exists now in the United States; she is a creditor nation with a big export trade, but she will not permit indiscriminate exchange. Modern financial methods are staving off such a crisis as followed the Napoleonic wars. The central problem is: When will the inability of war-damaged countries to pay for the material they require to restart their industries be felt by the nations supplying them? If trade balances are adjusted, the post-war slump will become a slow decline; otherwise, a crisis must occur when international obligations cannot be met. Another feature of the situation in the early part of the nineteenth century was the rapid growth in population observed everywhere. Official figures indicate the possibility of a repetition of this phenomenon.

Engineering.

Prof. C. F. Jenkin in his presidential address to Section G suggests that the time has come for an extensive revision of the theory of the strength of materials as used by engineers. The mathematical theory needs to be extended to cover anisotropic materials, such as timber, and to enable concentrations of stress such as occur at all changes of section to be calculated. Our knowledge of the physical properties of materials requires to be extended so that their suitability for all engineering purposes may be known. The need for the wider theory and for more research into the properties of materials is illustrated by examples of the problems which occurred in aeroplane construction during the war. The first material dealt with by the Air Service was timber. How was the strength of such material to be calculated? It was shown that th components of the tensile stress in three princip directions must not exceed the tensile strengths i those directions. Curves limiting the stress at an angle to the grain have been drawn for spruce, ash walnut, and mahogany. For plywood, "split-off veneers were recommended in place of "cut-off wood. The method used for the determination c Young's modulus for wood neglects the effect of shear and is therefore inaccurate. As an example of a isotropic substance steel is discussed. Fatigue limi is suggested as a measure of strength; in sample examined it was found to be slightly less than hal the ultimate strength. Research is necessary to deter mine the effects of the speed of testing, rest and hea treatment, and previous testing. For this improve methods are required; Stromeyer's method would b useful if modified for commercial use. Presen methods of testing in torsion are unsatisfactory, an knowledge of the internal mechanism of fatigu failure is required. For members of structures sub jected to steady loads a proof-load specification, whicl limits the permanent set to ⅓ per cent. or ¼ per cent is suggested. If fatigue limit is the basis for engine strength calculation, the distribution of stresses ii irregularly shaped parts of the machine must be inves tigated. Prof. Coker's optical method has beer applied to this end, but A. A. Griffith's calculation on the effects of grooves and polishing have not beer tested. Wood and steel are the only materials abou which trustworthy data have been collected.

Anthropology.

Prof. Karl Pearson in his presidential address t Section H urges the importance of anthropology, "th true study of mankind." Science should be studied not for itself, but for the sake of man. For this reason there is no use for the collection of measurements o height, span, size of head, etc. The important char acteristics are the psycho-physical and psycho-physio logical factors, reaction-time, mental age, and pulse tracing. Body measurement has no connection witl "vigorimetry" and psychometry, for no pure "line" in man has been traced. Moreover, present methods are entirely qualitative; they must be made quantita tive. Three things are urged as essential to the recognition of anthropology as a useful science. First folk-psychology as well as individual psychology should be studied as a means to determine race efficiency. For this purpose, the ancestry of man must be investigated in order that we may know which is likely to have the greater influence on his future, Nature or nurture. Secondly, institutes for the study of anthropology ought to be established in at least three of our universities. There the workers would be in touch with allied sciences, they would have a wide field open for measurements, and would be able to teach as well as to research on the subject. In this way men could be fitted for important "extra-State" work as diplomatic agents, traders, etc., in foreign lands. Another section of the work should be devoted to a study of the population at large; the schools, the factories, and the prisons must all be investigated, so that the present wasteful organisation of society may be remedied. When its value to the State has been proved, anthropology can ask for adequate support as its right. The third point urged is the adoption of a new technique. Logical accuracy and mathematical exactness must be introduced; training should start with anthropometry in its broadest sense, advancing later to ethnology, sociology, prehistory, and the evolution of man. Only by devotion to problems of real use can anthropology achieve her true position as "Queen of the Sciences."

Physiology.

Mr. Joseph Barcroft in his presidential address to Section I deals particularly with anoxæmia—by derivation a deficient quantity of oxygen in the blood—which is used to cover a larger field embracing all those conditions in which the supply of oxygen to the tissues is inadequate. The statement has been made that anoxæmia not only stops, but also wrecks, the machine. An inquiry into this statement cannot be made without first specifying whether the anoxæmia is sudden and profound, as in drowning, poisoning with mine-gas, etc., or is of long duration but trivial in degree. In the former case the stoppage of the machine may be almost complete, as in the case of persons rendered unconscious by carbon monoxide, by stoppage of the cerebral circulation, or by attaining an altitude in the air at which the oxygen pressure is too low. In such cases the permanent damage to the machinery is very slight. On the other hand, mild anoxæmia continued over weeks and months, as in sufferers from gas-poisoning, shallow respiration, and deficient ventilation of portions of the lung, is stated by Haldane, Meakins, and Priestley to produce far-reaching effects on the central nervous system. Anoxæmia may be classified as consisting of three categories. They are tabulated as follows, with examples:

ANOXÆMIA.

Types	I. Anoxic	II. Anæmic	III. Stagnant
Characteristics	Too little oxygen pressure and too much reduced hæmoglobin in arterial blood, which is too dark in colour	Too little oxyhæmoglobin, but normal oxygen pressure in arterial blood, which is bright unless discoloured by some abnormal pigment	Arterial blood normal in oxygenation, but blood flow too slow
Examples	Mountain sickness, pneumonia, etc.	Anæmia CO poisoning Methæmoglobin poisoning	Shock Back pressure

For a given deficiency of oxygen carried to the tissue in unit time the first type is the most serious, and the last least so. The anoxic type is measured by the percentage saturation of the arterial blood; the anæmic by the quantity of oxyhæmoglobin in it; and the stagnant by the "minute volume."

Botany.

Miss E. R. Saunders in her presidential address to Section K deals with the subject of Heredity. In the brief historical introduction attention is directed to the fundamental opposition between the earlier statistical methods of representing the hereditary process and the Mendelian conception which has its foundation in the act of sexual reproduction. Various complex relations which have proved capable of elucidation through the application of Mendelian principles are illustrated, and evidence is adduced in proof of the applicability of these principles to the case of specific hybrids. Certain cases are described where the unit for which the Mendelian factor stands appears to be a particular state of physiological equilibrium, and where lack of conformity of phenotypic appearance to genotypic constitution can be readily induced by a change in environmental conditions. The assumptions and difficulties involved in the explanations offered by the reduplication theory and the chromosome view respectively are discussed, together with the bearing of the evidence to date upon the question whether the same end-result, viz. segregation, may not be effected by a different mechanism, or at a different phase of the life-cycle, in different types. As a practical outcome greater co-operation is pleaded for between cytologists, physiologists, chemists, and breeders in attacking genetical problems.

Educational Science.

Sir Robert Blair in his presidential address to Section L directs attention to two of the wider aspects of present educational activities. The first part of the address is devoted to a general statement of the lines of advance and the success obtained in the application of psychology to the problems of education. The president, however, desires that education should become something more than applied psychology. The science of education "must be built up, not out of the speculations of theorists or from the deductions of psychologists, but by direct, definite, *ad hoc* inquiries concentrated upon the problems of the class-room by teachers themselves. When by their own researches teachers have demonstrated that their art is, in fact, a science, then, and not till then, will the public allow them the moral, social, and economic status which it accords to other professions." The second part of the address consists of an appeal to all voluntary effort to associate itself directly with the work of the local education authority. Sir Robert Blair thinks that our system of education will become national only when such national institutions as the public schools, the endowed grammar schools, and the universities have joined forces with the local education authorities and take a direct share in the solution of their problems. He seeks a form of association which will retain all the advantages of the older traditions.

Agriculture.

Prof. F. W. Keeble's presidential address to Section M is devoted to the subject of intensive cultivation. Commencing with a review of the work done by horticulturists during the war, it passes on to consider the prospects of success of any large development of intensive cultivation which may be undertaken. It insists on the great need for organisation in research, education, and administration, and describes the organisation which the author established during his tenure of the office of Controller of Horticulture in the Ministry of Agriculture. In this connection the important question of the relation of the "expert" and the "administrator" is considered, and the conclusion reached that "if the work of a Government office is to be and remain purely administrative, no creative capacity is required, and it may be left to the sure and safe and able hands of the trained administrator; but if the work is to be creative it must be under the direction of minds turned, as only research can turn them, in the direction of creativeness." The consideration of our imports, of the reduced acreage under fruit, and of the continuous rise in the standard of living throughout the world suggests that the acreage under fruit might be increased by a good many thousand acres without fear of over-production. After illustrating by a series of striking examples the effect which the practice of intensive cultivation has on bringing about the colonisation of the countryside, the address reaches the conclusion that it is the duty of the State to help the intensive cultivator to hold his own against world-competition by perfecting the organisation of horticulture, and, above all, by providing a thorough and practical system of horticultural education. The measure of success which intensive cultivation will achieve will depend ultimately on the quality and kind of education which the cultivators are able to obtain.

(*Continued from p. 812.*)

is to be taken as the normal weight of the animal, if we are to determine its surface from its weight? This fundamental question has hitherto defied solution, but is now brought into the realms of exact science, since the work of Prof. Dreyer and Dr. Ainley Walker (2 and 7) has shown that in animals and man definite relationships exist between the trunk length, chest circumference, and body weight of individuals in health, while no accurate relationship, as has long been realised by those familiar with the subject, can be traced between standing height and body weight.

The value of these measurements is enhanced by the fact that, as anatomical data, they will be practically immune from change in diseases which may be accompanied by a loss of weight, and, further, that as they bear a constant relation to the body weight, so must they bear a constant relation to the surface area of that animal.

The relationships which have definitely been shown to exist between "vital capacity," body weight, trunk length, and the circumference of the chest can be expressed by the following formulæ (8):—

(i) $\frac{W^n}{V.C.}=K_1$, where the power n is approximately $\frac{3}{4}$, though more accurately 0·72;

(ii) $\frac{\lambda^n}{V.C.}=K_2$, where the power n is approximately 2, though more accurately in males 2·26, in females 2·3;

(iii) $\frac{Ch^n}{V.C.}=K_3$, where the power n is approximately 2, though more accurately in males 1·97, in females 2·54;

while the relationships between body weight, trunk length, and circumference of the chest, respectively, can be expressed as follows:—

(iv) $\frac{W^n}{\lambda}=K_4$, where the power n is approximately $\frac{1}{3}$, though more accurately in males 0·319, in females 0·313;

(v) $\frac{W^n}{Ch}=K_5$, where the power n is approximately $\frac{1}{3}$, though more accurately in males 0·365, in females 0·284.

In all the above formulæ W = net body weight in grams, λ = trunk-length in centimetres, Ch = circumference of the chest in centimetres, and V.C. = vital capacity in cubic centimetres.

The procedures for taking the above-mentioned measurements, briefly described, are as follows:—

(i) Body weight = net weight, without clothes, in grams.

(ii) Trunk length in centimetres is taken by making the subject sit on a level floor with the knees flexed, the os sacrum, spine, and occiput being in contact with an upright measuring standard.

(iii) Circumference of the chest is taken at the nipple level in males, and just under the breasts in females, the subject being encouraged to talk and breathe naturally while the measurement is being taken.

(iv) The "vital capacity" in cubic centimetres is obtained by taking five consecutive readings with a suitable spirometer. The subject is instructed patiently and carefully how to proceed, and encouraged to make the maximum effort, the highest reading of the five measurements being recorded as the "vital capacity."

The relationships established by Prof. Dreyer, by the examination of individuals in perfect health, provide standards with which an individual or groups of individuals can be compared as regards two fundamental attributes, namely, "physique" and "physical fitness." These two attributes have hitherto been subject to the widest possible individual interpretation, and even in the judgment of one individual are liable to undergo monthly, if not diurnal, variations, dependent upon humour and an infinity of changeable circumstances in observer and observed.

Applying the standards determined for individuals in perfect health, it is found, as might have been expected, that different persons exhibit considerable deviations from these standards, particularly in respect to their "vital capacity," dependent upon their occupation and mode of life. Thus persons living a healthy outdoor life exhibit a greater "vital capacity" than persons following a sedentary occupation, and when this deficiency is *not* due to fundamental bodily defects it can be remedied by properly regulated training and outdoor life.

Critical examination of the available data has enabled Prof. Dreyer to grade the community, for all practical purposes, into three classes, A, B, and C, representing conditions of perfect, medium, and poor physical fitness. A classification on such lines is essential when any degree of accuracy is required in the determination of the aberrations from normal met with in disease. It would obviously be unjustifiable in disease (9) to apply A class standards to the individual who, by reason of his occupation and mode of life, belongs in normal health to C class. The consideration of this aspect of the question, however, need not detain us longer, as being outside the scope of the present article.

It is extremely difficult in so brief an account to do full justice to the immense significance and the great possibilities which lie behind this recent work of Prof. Dreyer's, but sufficient, it is hoped, has been said to show that by systematic measurement of "vital capacity" and the body measures herein discussed, in adults and adolescents, it should be possible to ascertain what detrimental or beneficial effects environment and occupation exert upon the development and health of the individual. Further, it is clear that most important information, from the point of view of national health, should become available in connection with the methods employed to ameliorate the conditions

of those who show deficiencies from the standards obtaining in conditions of perfect health.

The British Association at Cardiff.

THE eighty-eighth annual meeting of the British Association opened at Cardiff on Tuesday morning, in the very unfortunate circumstances of a general strike of tramwaymen and some other sections of the city workmen. It is to be feared that as, unfortunately, paragraphs about this found their way into the Sunday newspapers, this local trouble has had the effect of diminishing the attendance at the meeting. Members and intending members might have rested assured that the city of Cardiff would rise to the occasion. The local secretaries immediately arranged a British Association motor service for the use of members, but it appears that no inconvenience was felt by those who are attending the meeting, and most of the services have now been withdrawn.

It is not possible at the moment of writing to give exact figures of the membership, but it exceeded 1200 on Tuesday morning, so that a fair average meeting was even then certain, in spite of the strike. The weather, always inclined to be wet in this part of the country, and particularly atrocious during the present summer, has taken a turn for the better, and the visitors have had the opportunity of seeing the sun in Cardiff, when the residents had almost forgotten its existence.

The citizens' lecture on "Light and Life," by Prof. J. Lloyd Williams, of University College, Aberystwyth, in the Park Hall, on Monday evening, attracted a large audience, notwithstanding that many of those present had to face a long walk home.

At the inaugural general meeting on Tuesday evening, when Prof. Herdman delivered the illuminating address published in full elsewhere in this issue, the retiring president, Sir Charles Parsons, read a message which the council had sent to the King offering, at this meeting in Wales, the grateful congratulations of the Association for the inspiring work done for the Empire by the Prince of Wales during his Australasian tour. Sir Charles Parsons read also messages of condolence sent to relatives of Prof. J. Perry and Sir Norman Lockyer at the loss sustained by the recent deaths of these two distinguished representatives of British science—one of whom was general treasurer of the Association from 1904 until his death, while the other was president in 1903–4.

At the meeting of the general committee on Tuesday, the report of the council was adopted nominating Sir Edward Thorpe as president of the Association for the meeting next year in Edinburgh, and Sir Charles Parsons as a permanent trustee, in succession to the late Lord Rayleigh.

The whole of the presidential addresses are this year published in volume form under the title "The Advancement of Science, 1920," at the price of 6*s*., or 4*s*. 6*d*. to members at the meeting. The volume makes a valuable record of the progress and position of many departments of science, and of authoritative conclusions concerning them.

Whilst the meeting is not likely to rank as a "record," the members present are very keen, and everything possible to ensure its success is being done by the city authorities and local Press.

The palatial apartments of the City Hall are being used for the reception room and other offices, whilst in the University College and Technical College near by all the sections are provided with excellent accommodation. The Park Hall, in which the president's address, the evening discourses, and the citizens' lectures are delivered, has a seating capacity of well above 2000, and everyone present has an uninterrupted view and hearing.

The numerous sectional and the two general excursions have not been interfered with by the strike, as they rely chiefly on road or railway transport.

R. V. S.

Sir Norman Lockyer's Contributions to Astrophysics.

By Prof. A. Fowler, F.R.S.

By the death of Sir Norman Lockyer the science of astrophysics has lost the energising and stimulating influence of the last of the great pioneers whose labours opened the way to so vast an extension of our knowledge of the universe. The science of celestial chemistry and physics had its real beginning in 1859, when Kirchhoff's famous experiment on the reversal of spectral lines furnished the key to the interpretation of the dark lines of the solar spectrum, and thence to the determination of the composition of the sun and stars. During the earlier years the outstanding features in the development of the new science were the brilliant investigations of Huggins on the spectra of stars and nebulæ, and those of Rutherfurd and Secchi on the spectroscopic classification of the stars. Curiously enough, the sun had received but little attention during this period, and Lockyer was practically entering a virgin field when, in 1866, he attached a small spectroscope to the modest 6-in. equatorial of his private observatory, and observed the spectrum of a sun-spot independently of the rest of the solar surface. Simple as it may now seem, this process of "taking the sun to bits," as Sir Norman used to call it, was an advance of fundamental importance. It not only gave an immediate and decisive answer to the question as to the cause of the darkness of sun-spots which was then under vigorous discussion in England and France, but also very soon led to the famous discovery of the method of observing solar prominences without an eclipse, with which Lockyer's name, in conjunction with that of Janssen, will for ever be associated. The story of this epoch-making observation has been told too often to need repetition, but it should not be forgotten that the principle of the method had been clearly recognised by Lockyer two years before he succeeded in obtaining a spectroscope suitable for the purpose in view.

Those who have become familiar with the beautiful solar phenomena presented by this method of observation will best understand the enthusiasm and delight with which Lockyer continued his observations whenever the sun was visible. On the first day of observation—October 20, 1868—he had identified the C and F lines of hydrogen, and a yellow line near D, in the spectra of the prominences, and on November 5 he discovered that the prominences were but local upheavals of an envelope entirely surrounding the photosphere, to which he gave the name of the *chromosphere*, as being the region in which most of the variously coloured effects are seen during total eclipses of the sun. The peculiarities of the bright F line at once suggested to his fertile mind that the spectroscope might disclose the physical state, as well as the chemical composition of the chromosphere and prominences, through the medium of laboratory experiments, and from this beginning the close association of the laboratory with the observatory became the dominant note in his life's work. His first experiments were made in collaboration with his friend Frankland, and it was shown that the widening of the F line at the base of the chromosphere was to be accounted for by an increase of pressure. These experiments further demonstrated that the yellow line of the chromosphere, which had been named D_3, was quite distinct from hydrogen, and the then unknown gas to which it was to be attributed was given the now well-known name of *helium*. Up to the year 1873, however, Lockyer's work was carried on almost entirely in his private observatory, and in the laboratory which he had established in his house at Hampstead. He not only continued his solar observations with conspicuous success, but also commenced his well-known "Researches on Spectrum Analysis in Connection with the Spectrum of the Sun," in which he developed experimental methods which afterwards became common practice.

On his transfer to South Kensington, with which his connection continued for forty years, the facilities at Lockyer's disposal for research were at first very meagre, but additions to equipment and staff were made from time to time, and in the later years the observatories and laboratories were well adapted for their special purposes. Lockyer's dream of becoming director of a permanent astrophysical observatory, comparable with those established by Governments in other countries, however, was never realised, and his work throughout was carried on in temporary buildings, and for the greater part of the time with modest grants in aid from year to year. In 1912, on the transfer of the Solar Physics Observatory to the control of the University of Cambridge, Lockyer, in spite of his weight of years, courageously set about the erection of a new observatory at Sidmouth, and continued his work on stellar spectra almost to the close of his life. It is a lamentable fact that much of his time and energy was almost continually taken up with a struggle to obtain adequate means to carry on his researches.

The contributions to astrophysics made by Lockyer during nearly sixty years of strenuous endeavour in its various fields of investigation form the subject-matter of more than 200 papers and memoirs, and it is only possible here to refer to some of the larger questions in which he was specially interested. His work, both in the laboratory and in the observatory, was largely guided by bold speculations, which he was usually careful to regard as working hypotheses, and from time to time the main points were brought together

in appropriate sequence in the form of books, among which are "The Chemistry of the Sun" (1887), "The Meteoritic Hypothesis" (1890), and "Inorganic Evolution" (1900). His observations and his views on their significance were thus made widely known, and the trend of his work could be the more readily followed. It was especially his desire to impress upon chemists and physicists the importance of the sun and stars as a means of investigating the behaviour of matter at high temperatures, and as possibly throwing light upon the nature of atoms and molecules.

Among the researches which have had the most potent influence, and have led to very definite advances, were those which dealt with the changes in the spectrum of the same element under different conditions of experiment. Lockyer was early led by his solar observations to a comparative study of the flame, arc, and spark spectra of some of the metallic elements, and one of his first successes was to show that some of the lines most characteristic of solar prominences, other than those of hydrogen and helium, were produced only under high temperature conditions, while some of those prominently affected in sun-spots were produced at a low temperature. With these and other observations as a basis he put forward, in 1873, his well-known dissociation hypothesis, which became the subject of much discussion. The hypothesis supposed that at successively higher temperatures the "molecular groupings" which existed at lower stages were broken up into finer forms of matter, or possibly into new elements, producing different spectral lines, and on this view it was shown that a multitude of solar observations which had seemed to be wholly inexplicable on the ground of previous laboratory experience became easy of explanation. Thus his view of the construction of the solar atmosphere was that if we could observe a section of it we should see it divided into a number of layers, each with its appropriate spectrum, and the spectrum would be simpler the nearer the layer was to the photosphere. The metallic elements, instead of existing as such in a reversing layer, were considered to be entirely broken up in the vicinity of the photosphere, and their germs distributed throughout the atmosphere, the molecular groupings becoming more complex as they became further removed from the source of heat. The theory doubtless calls for some re-statement in the light of modern views as to the structure of atoms and the origin of spectra, but it was a valuable guide to observation, and Lockyer anticipated the conclusion reached by St. John in recent years, that the complete absorption of any one element in the solar spectrum is the integration of lines special to various levels in the solar atmosphere. Lockyer himself seems to have been convinced that the ultimate products of dissociation were hydrogen and helium; but although this is so closely in accord with recent work on the structure of atomic nuclei, it does not seem probable that the phenomena studied by Lockyer were directly related to those investigated by Rutherford. The writer well remembers numerous attempts to produce the lines of hydrogen or of helium by the passage of powerful condensed discharges between metallic electrodes, all of which, however, were unsuccessful.

Work on the varying spectra of the elements was vigorously resumed by Lockyer in connection with the interpretation of the photographs of the chromospheric spectrum which had been taken under his direction during the solar eclipses of 1893 and 1896, and of a series of photographs of stellar spectra which he had commenced at Kensington about 1890. Several elements were investigated over a long range of spectrum, and numerous additional lines were found to be intensified on passing from the arc to the spark spectrum, or which only appeared in the spark. These were designated "enhanced lines," and the work at once led to the definite assignment of origins to many chromospheric and stellar lines which had previously resisted explanation. But this was not all; the enhanced lines were shown to belong to a special class which were only fully developed at high temperatures, so that they gave valuable evidence of physical conditions in the atmospheres of the sun and stars as well as of their chemical constitutions. It would scarcely be too much to claim that this further work on enhanced lines introduced a new principle into astronomical spectroscopy, inasmuch as it justified the chemical identification of celestial spectra which could not be completely reproduced in the laboratory. The only assumption it was necessary to make was that the series of changes indicated in the flame, arc, and spark would be continued if still more powerful means of excitation were available, so that at sufficiently high temperatures the enhanced lines would be the sole survivors. In accordance with his views on dissociation, and for convenience of reference, the enhanced lines were designated "proto-metallic" lines, and attributed to "proto-metals," which were regarded as simplified forms of the vapours which yielded the arc lines.

Apart from any special views as to the cause of their appearance, however, the discovery of enhanced lines has proved to be of the first importance in astrophysical inquiries, and the tables of such lines which were compiled at South Kensington have been much utilised by astronomers throughout the world. Among other applications, as Lockyer was the first to show, the interpretation of the spectra of new stars in their early stages is almost entirely dependent upon a knowledge of the enhanced lines of iron, titanium, and other elements. In collaboration with his assistants, Lockyer showed later that enhanced lines were also developed under the action of strong electrical discharges in non-metallic elements, including silicon, carbon, sulphur, and nitrogen, and the lines observed in these experiments have also led to important celestial identifications. There can be little doubt that the continuation of

these investigations, as in Fowler's experiments on helium and oxygen, and Merton's further work on carbon, will yield results of high value in the interpretation of the spectra of stars at the highest stages of temperature, and possibly also of the nebulæ.

Another of the chief subjects which attracted Lockyer during a great part of his life was the classification of stellar spectra, and the order of celestial evolution which might be inferred. He was at first mainly dependent upon stellar observations made by others, but he soon saw the necessity for first-hand data, and, following Pickering's remarkable success with the objective prism, he adopted this form of instrument in most of his work at Kensington, and afterwards at Sidmouth. He early adopted the suggestion made by Tait that in nebulæ and comets the luminosity may be due to solids heated by impact, as well as to heated gas generated by the impacts, and about 1887 developed it into his "meteoritic hypothesis." The fundamental idea is that all self-luminous celestial bodies are composed either of swarms of meteorites, or of masses of meteoritic vapour produced by heat, the heat being developed by condensation due to gravity, and the vapour being finally condensed into a solid globe. The classification of stellar spectra which he based upon this theory has undergone modifications in detail, chiefly in the direction of subdivision and more complete definition of the criteria for the various stellar groups; but the essential idea has remained unchanged throughout. In common with other astronomers, Lockyer adopted the view that the spectroscopic differences between the various classes of stars are mainly due to differences of temperature, but, unlike most of them, he insisted that in place of a single line of evolution from hot (white) to cool (red) stars the progression must be from cool to hot stars and back again to cool stars. That is, in accordance with the theory of condensing swarms of meteorites or masses of gas, the classification made a distinction between stars of increasing temperature and those which are on the down-grade towards the extinction of luminosity.

Some of the earlier evidence for the separation of the stars on the two branches of the "temperature curve" which Lockyer pictured may be of doubtful validity, but the valuable photographic data accumulated later, in combination with laboratory researches, placed his classification on a much firmer basis. It was found, for example, that when stars at any given stage of temperature were brought together by reference to the relative intensities of enhanced and arc lines, they were definitely divisible into two groups, showing that the spectra were dependent in part upon physical conditions other than those imposed by temperature alone. This difference was attributed to differences in the state of condensation, one group being less condensed than the other, and therefore to be considered as being in an earlier stage of evolution, notwithstanding equality of temperature. The Harvard classification, which has been adopted by most astronomers, is along one line of temperature only, and accordingly disregards this difference. It is clearly of great importance, however, that the difference should be taken into account in questions relating to stellar distribution and other matters connected with the structure of the sidereal universe, and it was a source of profound regret to Lockyer that greater attention was not given to it. In the case of the helium stars, however, Lockyer's classification has received substantial corroboration from a discussion by Herassimovitch of their radial velocities and absolute magnitudes, in which the catalogues of Lockyer were utilised. Among the results it was shown that the stars which Lockyer had located on the ascending branch of the temperature curve were brighter than those on the descending branch, and, assuming the average masses to be equal, it would follow that the former were of greater volume and lower density than the latter, in accordance with Lockyer's hypothesis.

The theory of stellar evolution put forward a few years ago by Prof. H. N. Russell resembles that of Lockyer in its main outlines, though based mainly on deductions as to the densities and absolute magnitudes of the stars. The criteria are thus somewhat different in the two cases, but there can be little doubt that in one form or other the recognition of an ascending, as well as of a descending, line of stellar temperatures will take an important place in the astronomy of the future.

The observation of total eclipses of the sun also occupied much of Lockyer's attention. He personally took part in nine eclipse expeditions, and was responsible for several others in which the observations were undertaken by his assistants. On several occasions, when H.M. ships were detailed to assist the expeditions, his exceptional organising ability enabled him effectively to utilise the services of officers and men so as to cover the widest possible range of observations. The outstanding feature of his work in this connection, however, was the introduction and use, first of a visual spectroscope without slit or collimator, and afterwards, when photographic methods could be adopted, of the prismatic camera. With instruments of this type he was able clearly to differentiate between the coronal and chromospheric radiations, and, besides detecting several new coronal lines, he obtained splendid records of the "flash" spectrum. He was thus able to determine the various heights to which the different vapours extended, and he identified a multitude of the bright lines with enhanced lines which he had so diligently investigated in the laboratory.

Lockyer would have been the last to claim that his work was wholly free from errors, but it was almost invariably of a stimulating character, and has played a leading part in the development of the science of astrophysics practically from its very beginning. Much of his work will have an enduring place in the history of the science to which he devoted his great gifts.

Notes.

THE triennial prize competition for the best original contribution to the scientific advance or the technical progress of electricity, known as the Fondation George Montefiore Prize, and administered by a committee of the Association of Electrical Engineers from the Montefiore Technical Institute of Liége, which had lapsed during the war, is now to be revived, and the competition which would have been held in 1917 is now announced for 1921. The prize will amount to 20,000 francs. Competitors must send in their work by April 30, 1921, and all particulars can be obtained from the Secretary, Fondation George Montefiore, rue Saint-Gilles 31, Liége, Belgium. Contributions may be in English or French, and if successful are published in French in the *Bulletin de l'Association des Ingénieurs Electriciens sortis de l'Institut Technique Montefiore.*

NELA RESEARCH LABORATORY was organised in 1908 under the directorship of Dr. Edward P. Hyde as the physical laboratory of the National Electric Lamp Association. The name was changed to Nela Research Laboratory in 1913, when the National Electric Lamp Association became the National Lamp Works of the General Electric Co. For some years the laboratory was devoted exclusively to the development of those sciences on which the art of lighting has its foundation, but in 1914 the functions of the laboratory were extended by the addition of a small section of applied science which had an immediate practical objective. The section of applied science is now being largely extended as a separate laboratory of applied science under the immediate direction of Mr. M. Luckiesh, who becomes director of applied science, and a new building is being constructed to house this branch of the work. Dr. Ernest Fox Nichols, formerly president of Dartmouth College, and more recently professor of physics at Yale University, has accepted an invitation to assume the immediate direction of the laboratory of pure science under the title of director of pure science. The work of this laboratory, which will be continued in the present building, will be somewhat further extended under the new organisation. The laboratory of pure science and the laboratory of applied science will together constitute the Nela Research Laboratories, and will be co-ordinated under the general direction of Dr. Hyde, who becomes director of research.

THE Public Health Department of the Portsmouth Town Council, having evidently investigated thoroughly the scientific evidence submitted to it on the practicability of preventing the infection of venereal disease by the use of a disinfectant immediately after exposure to risk, has recently issued two descriptive leaflets giving the information necessary to carry out the disinfectant process effectually. We understand that about a dozen other Health Departments are taking, or about to take, similar measures. The leaflets, entitled "What Every Man should Know," embody in clear words the ascertained knowledge on this matter which has been acquired by observation and experiment, and contain a succinct and useful summing-up of the multiform evils of venereal disease. The council states that it has come to the conclusion that, in view of the terrible effects of this disease on national and family life, it is its bounden duty to make public a knowledge of the means by which this scourge can be prevented. These leaflets pay due regard to both the social and scientific aspects of the much-discussed subject of prompt self-disinfection after incurring the risk of infection. The Portsmouth Public Health Department deserves to be congratulated on its action in this seriously important matter of sanitation.

"EPIDEMIC stupors" are often referred to in early records (seventeenth and eighteenth centuries) as occurring in times of influenza prevalence, and in this country encephalitis lethargica made its appearance immediately before and during the influenza epidemic of 1918–19. It is of interest, therefore, to record the occurrence of the same disease in Karachi at the end of 1919 during an epidemic of influenza. A full description of the outbreak, consisting of seventeen cases, is given by Capts. Malone and Maitra in the *Indian Journal of Medical Research* (vol. vii., No. 3).

IN the Journal of the Royal Society of Arts (vol. lxviii., No. 3533, August, 1920) we have a report of the Sir George Birdwood memorial lecture on "The Enduring Power of Hinduism" by Sir Valentine Chirol. Sir Valentine admits that he writes "not as a student, but merely as a layman." He has, however, been a diligent student, and his wide knowledge of contemporary politics and his experience of personal visits to many of the most important sites where archæological investigation is being conducted by Sir John Marshall have enabled him to construct a graphic picture of the historical development of India in relation to Hinduism. This lecture is thus of considerable importance, and it is rendered more attractive by the picturesqueness of the author's style. He has not followed so completely the trend of modern studies as to grasp the fact that the survival of Hinduism, in spite of the rise of Buddhism and the cataclysm of the Mohammedan invasion, is due to its amorphous character, its eclectism, and its capacity for adapting itself to novel conditions. But with these reservations the lecture gives an admirable account of the development of Hinduism.

THE character of the prehistoric culture of the people of the Malay Peninsula has as yet received inadequate attention, but much good work is being done in continuation of that summarised in "The Pagan Races" by Messrs. Skeat and Blagden. Thus we find in the Journal of the Federated Malay States Museum (vol. ix., part 1, January, 1920) an excellent account by Mr. I. H. N. Evans of the exploration of a rock shelter in the Batu Kurau Parish, Perak, with a description of the flint-weapon industry. In more recent times the influence of Islam has been predominant, but it has absorbed and assimilated much of the indigenous animistic beliefs. In this connection, in the same issue of the journal, Mr. R. O. Winstedt refers to some curious analogies between the local customs and those of the Brahmans of South

India, which point to the widespread influence of Hinduism in the peninsula prior to the establishment of Islam as the dominant faith.

MR. HENRY BALFOUR has reprinted his interesting presidential address from the Proceedings of the Somersetshire Archæological and Natural History Society (vol. lxv., 1919, pp. xxiii *sqq.*). He claims connection with Somersetshire on the ground that his late colleague, Sir E. B. Tylor, was a Somersetshire man by birth, and that Mr. H. St. G. Gray, now curator of the Taunton Museum, was his own assistant at Oxford. In his address Mr. Balfour crosses the county border to Rushmore and Cranborne Chase, on the border of Wilts and Dorset, the home of a great archæologist and ethnologist, Col. Pitt Rivers. He closes his review of this notable man with the remark that "he has left his own record of diligent and broad-minded research, and the example afforded by his enthusiasm, characteristically tempered with caution, should have the effect both of stimulating and of restraining the work not only of this generation, but of generations to come."

THE Quarterly Summary for July issued by the Royal Botanic Society of London contains notes on some plants of interest in the gardens. The gigantic floating leaves of the *Victoria regia* water-lily are now 7 ft. in diameter, and, as each new leaf at this time of year exceeds its predecessor, it seems likely that they will reach the maximum of $8\frac{1}{2}$ ft. by the end of August. As the sunlight becomes less the new leaves get smaller, until the plant dies down in October. One of the earliest accounts of this remarkable tropical American water-lily was that given by Lindley in the Proceedings of the society in 1839 (vol. i.). The plant was discovered by Robert Schomburgk, the traveller, on the River Bernice, in Guiana, and the detailed description which he sent home was sufficient to enable Lindley to recognise it as a distinct genus of water-lilies, which was, by permission, dedicated to the young Queen. Efforts to grow the plant at Kew were at first unsuccessful, but in 1849 some fifty plants were successfully raised from seed and distributed to various gardens. The fine specimen growing at Kew is one of the most popular attractions of the Royal Gardens. Another interesting plant in the same tank at the Botanic Gardens is the Lotus, *Nelumbium speciosum*, which has flowered profusely this year. Its large salver-shaped leaves and tall pink flowers rising from the water present a striking appearance. The plant was held in esteem by many ancient peoples in the East; in Egypt paintings of it decorate the temples, and it is still associated with temples in India, where the long, fleshy roots are eaten as well as the oval, nut-like seeds. The society has also been making experimental growths of the soya bean, with the view of ascertaining the most suitable variety for cultivation in this country.

AMONG the recently issued reports of the Canadian Arctic Expedition, 1913–18, are two on the Crustacea, which form part of vol. vii. An account of the marine Copepoda is given by Prof. Arthur Willey (in Part K) and of the Cladocera by Dr. Chancey Juday (in Part H). Cladocera have been examined previously from Greenland and from Alaska, but not from the intervening region of Arctic America. Seven fresh-water and two marine species are recorded, all of which are well known and have a wide geographical range. The fresh-water species belong to the genera Daphnia (*pulex* and *longispina*), Bosmina, Eurycercus, Alona, Chydorus, and Polyphemus, and the marine species to Podon and Evadne respectively. The common *Daphnia pulex* is also recorded from Polaris Bay, Greenland, about 82° N. latitude, where it was collected by the United States North Polar Expedition on August 1, 1872. This seems to be the most northerly record for any of the Cladocera. The material of this species from Polaris Bay consists of several hundred specimens, the great majority being females with ephippia. The specimens of *Daphnia pulex* in the various catches of the Canadian Expedition show that the winter eggs in the ephippia probably hatch during the latter half of June; that females bearing parthenogenetic or summer eggs appear about the first week in July; and that males and ephippial females make their appearance in late July and in August. The season is therefore a relatively short one

A NOTEWORTHY contribution to the study of that fascinating group of insects, the parasitic aculeate Hymenoptera, is made by Prof. W. M. Wheeler in the Proceedings of the American Philosophical Society (vol. lviii., 1919, No. 1). Prof. Wheeler gives a comprehensive summary of the subject, citing and criticising a long array of literature, and discussing the evolution of the parasitic habit. He is disposed to regard the aculeate parasites as originating directly or indirectly from the insects which serve as their hosts. "The object of the parasite is to secure the provisions accumulated by the host for its own progeny. This involves a destruction of the egg or young larva of the host." But a higher specialisation is reached by the social insects which foster the host-brood so that their own young may be reared and fed.

ANATOMICAL details of some morphological importance are elucidated by Prof. G. H. Carpenter and Mr. F. J. S. Pollard in a recent paper (Proc. R. Irish Acad., B, vol. xxxiv., No. 4) on the presence of lateral spiracles in the larvæ of warble-flies (Hypoderma). Six pairs of these vestigial structures, suggesting a primitive peripneustic condition of the respiratory system, are recognisable in the ripe warble-maggot, connected with the outer lateral tracheæ by fine, thread-like, solidified air-tubes.

DR. E. H. PASCOE, of the Geological Survey of India, revived at a meeting of the Geological Society of London in March, 1919, in a new form the question of the relations of the Indus, the Brahmaputra, and the Ganges (Quart. Journ. Geol. Soc., vol. lxxv., p. 138, 1920). He traces back the now divided system to a river, the Indobrahm, the headwaters of which were in, or soon cut back into, the Brahmaputra region of Assam, while the mouth was in the Indus region of the Arabian Sea. This river

originated in the beginning of the Siwalik epoch, when the depression at the foot of the Himalayas ceased to be the scene of conflicting lagoon and terrestrial conditions, and became finally silted up. The great river was guided along this depression westward, while a contemporaneous river ran on the Tibetan side of the range, of which the alluvium remains from Pemakoi, north-east of the Bay of Bengal, to Gilgit, north of the great Indus bend. This river joined the Oxus, or reached the Arabian Sea by an independent course. It is urged that the Indobrahm captured the upper waters of the northern river by cutting back into them along its tributaries at successive points in the recesses of the range from which the Indus now runs south-westward. The speakers in the discussion of the paper, including Mr. R. D. Oldham, approved the main geographical contentions, but laid more stress than the author on earth-movements in determining the diversions and the courses of the tributaries through the hills.

SIMULTANEOUSLY with the investigations of Dr. Pascoe, Dr. G. E. Pilgrim, of the Geological Survey of India, put forward his suggestion of a great Pliocene river running on the south side of the Himalayas from Assam to the Indus course. Dr. Pilgrim's paper and maps (Journ. Asiatic Soc. of Bengal, vol. xv., p. 81, 1919) appeared, indeed, before the printing of Dr. Pascoe's work, and, as that author points out, the argument based on the direction from which the tributaries meet their primaries in the mountain-belt originated with Dr. Pilgrim. The two papers should be read together, and they form a great addition to our conceptions of the past geography of India. Dr. Pilgrim gives prominence to earth-movements as promoting the dislocation of the Assam-Punjab or Siwalik River. His maps of Western Asia in Eocene, Miocene, and Pliocene times are highly useful.

THE "Fossils from the Miura Peninsula and its Immediate North" form the subject of an important memoir by Prof. M. Yokoyama (Journ. Coll. Sci., Tokyo Imp. Univ., vol. xxxix., art. 6, pp. 193, 20 pls.). The geological formations of the peninsula are in part undoubtedly Pliocene, and in part either Pliocene or Pleistocene; those of the plain are divisible into an upper, sub-aerial, and a lower marine series several hundred feet in thickness. The sub-aerial series is made up of a brown loam, an altered volcanic ash, wholly devoid of stratification and organic remains. The marine series, which the author names the Musashino formation, is divisible into an upper and a lower series. In the upper, remains of *Elephas namadicus*, Falc. and Caut., are not uncommon, and are perhaps the most important of the fossil contents. The Lower Musashino beds are provisionally divided by the author into six zones. From the whole series, 232 species of Mollusca and 6 of Brachiopoda are recorded, 91 of the former and 2 of the latter being described as new; the whole are well illustrated, but the nomenclature, as, alas! too generally the case in papers of this class, lags behind the times. The number of forms not known to be living is 88, or about 37 per cent. of the whole fauna, and 7 species have not yet been found in Japanese waters. The author therefore classes these Musashino beds as Pliocene of about the same age as the English Red Crag of Newbourne=Austelien of the Netherlands.

THE *Geologische Reichsanstalt* of Vienna, which was able in Imperial times to spread the influence of a great school of geology over Polish, Transylvanian, and Dalmatian lands, has been forced to adopt, from the opening of 1920, the restricted title of *Geologische Staatsanstalt*. Dr. Emil Tietze, the director, retires after long and honourable service, recognising in the "geschickte Diplomatie des Königs Eduard von England" the prime cause of the restriction of his official field. The *Verhandlungen* for 1919 indicate many changes on the staff, some workers whose names are familiar having become aliens through territorial readjustments. We must hope that their common science will maintain the federal spirit shown in the last publications of the *Reichsanstalt*. Many of the papers deal with mountain structure. Dr. F. Heritsch claims that the discovery of tabulate corals in the supposed Mesozoic mantle of the Hohe Tauern disposes of the idea that the mass has been imported by overfolding, and we may be prepared for continued criticism in Austria of the theory of recumbent folds in general. Dr. O. Ampferer, who becomes one of the *Chefgeologen* and also a *Bergrat*, contributes a paper in his lucid and systematic manner on the very considerable influence that deep notches (*Kerben*) cut by erosion may have on tectonic features when a region comes under processes of crust-folding.

CHEMICAL as well as geological workers will welcome a new and enlarged edition of W. F. Hillebrand's "Analysis of Silicate and Carbonate Rocks" (Bull. 700, U.S. Geological Survey, 1919). The accurate methods described are obviously of service in the analysis of potassium silicates and refractories for commercial use, as well as in the refined discrimination of types of natural rock. The importance of the estimation of small quantities of unusual or commonly overlooked constituents is here pointed out. At the same time this may be quite unnecessary in many cases of ordinary practice, and for these a system of "condensed analysis" is charitably described in the concluding pages.

AN interesting example of the applications of zonal palæontology is afforded by Messrs. F. L. Kitchin and J. Pringle, who show (*Geol. Magazine*, vol. lvii., pp. 4, 52, and 100, 1920) that a mass of Gault and Cenomanian strata at Shenley, near Leighton Buzzard, 250 yards long and 150 yards wide, has been inverted on Lower Greensand. The fossils provide the clue, being in inverse succession to those in the undisturbed beds of the neighbourhood. As a boulder pushed by ice, this presents some parallel with the famous block described by Mr. R. G. Carruthers in the heart of Caithness (NATURE, vol. lxxxix., p. 229), in which a quarry has been opened 160 yards in length.

THE occurrence of barytes in the upper parts of lodes containing metallic sulphides is probably well recognised, and postulates an infiltration of barium chloride upwards during the formation of the lode or downwards to meet the sulphates that are in solution. Mr. H. W. Greenwood suggests (Proc. Liverpool Geol. Soc., vol. xii., part 4, p. 355, 1920) that the barytes which is common in the English Triassic strata, and mainly found in the upper beds, was derived from overlying Jurassic strata. The source of an exceptional quantity of barium in the Jurassic seas is not indicated. Might it not have been brought into the Triassic pan-deposits from the denudation of our Armorican lode-formations?

IN a general "Review of the Reptilian Fauna of the Karroo System" (Trans. Geol. Soc. S. Africa, vol. xxii., p. 13, 1920) Mr. S. H. Haughton concludes that the preservation of complete skeletons of Pareiasaurians in the beds south of Prince Albert Road station was determined by a rapid deposition of fine mud or silt. In the discussion on this paper (Proc. *ibid.*, p. xli.) Dr. van Hoepen supported, by his personal observations on the skeletons of various genera, the view of entombment in swampy lakes rather than, as Mr. Watson had suggested, in windborne sand. Dr. du Toit stated that he was unwilling to return to the old supposition of a general Karroo lake in Lower Beaufort times, but he pictured a surface "that became periodically inundated and, at certain stages, semi-arid in climate."

THE present summer has so far experienced some disturbing weather anomalies, the abnormal features being chiefly the persistent low temperatures and the frequent heavy rains. Some improvement has been generally experienced during the present month owing to the greater prevalence of anticyclonic conditions. A disturbance, however, traversed the north of Ireland and the southern portion of Scotland on the night of August 17 and the early part of August 18. The storm area followed a track fairly due east, and was preceded and accompanied by a heavy downpour of rain which occasioned considerable damage in Edinburgh and the surrounding neighbourhood. The rainfall at Edinburgh for the twenty-four hours to Wednesday morning was 3·1 in., and in twelve hours the fall amounted to 2 in. At Leith the fall in twenty-four hours was 2·84 in., and at Renfrew 2·80 in. A subsidiary disturbance occasioned heavy rain in the south of England, and at Falmouth the fall was 2·21 in. between 8 a.m. and 7 p.m. on August 18. Very cool northerly winds spread over the country in the rear of these disturbances. On the morning of August 20 frost occurred on the ground in the open in Scotland and in parts of England, whilst in places the thermometer in the screen fell to 36°. At Greenwich the exposed thermometer registered 33° and in the shade 41°, which was only 3° above the lowest figure reached in August since 1841, 38° being recorded in 1864, when the exposed thermometer fell to 27°. At Kew it was the coldest August night since 1891, and at Falmouth it was as cold as any time in August during the last half-century.

AMONG recent pamphlets issued officially by the Meteorological Office under the heading of Professional Notes is one by Mr. J. S. Dines entitled "Methods of Computation for Pilot-balloon Ascents." Without claiming to be exhaustive, this gives some account of, at any rate, the better-known methods of determining wind velocities at different heights. Part i. deals with the most practised single-theodolite ascents, and nine methods are described, including those in general use by the military Meteorological Services of France, Italy, and the United States, partly graphical and partly depending upon a special slide-rule. The ideal method for open-air work discards the graphical method so far as possible. Part ii., dealing with double-theodolite ascents, gives six methods of dealing with these, including, as does part i., the Meteorological Office method, which depends entirely on the slide-rule. Part iii., on balloon-tail, gives two graphical methods besides the Meteorological Office slide-rule plan. Perhaps more interesting than any of these is the appendix dealing with various methods of obtaining velocities at heights when cloud-sheets prevent the observation of pilot-balloons. The smoke from anti-aircraft shells set to explode at a given height can be observed through a comparatively small break in the cloud, and even when the cloud-sheet is quite unbroken the position of bomb-bursts can be determined by sound-ranging from the ground or by observation from an aeroplane.

IT was scarcely likely that proposals so far-reaching in effect and importance as those put forward by the Egyptian Ministry of Public Works for the extensive development of the cultivable area of the valley of the Nile by the construction of a dam and other irrigation works should escape a large measure of hostile criticism, and we have on several occasions alluded to the attacks made by Sir William Willcocks on the validity and trustworthiness of the data on which the scheme is founded. These attacks, it will be recalled, led to the appointment of a Special International Commission of Inquiry, which has had the projects under review. We have now received a copy of a brochure issued by an independent Commission of Native Egyptian Engineers, who take up an attitude of strong and uncompromising opposition to the official proposals on the grounds that there are obvious inconsistencies in the fundamental calculations, and an evident tendency on the part of the Technical Adviser to the Egyptian Government to "adapt" his data to the requirements of the case. The objectors state that they fear that any attempt to cut off or decrease the supply of water and silt to Egypt from the Blue Nile will be fraught with disastrous consequences, and they set out their arguments in a series of sixteen criticisms of the official scheme. An addendum by Dr. Mahgoub Sabitt, professor of medical jurisprudence and toxicology at the Egyptian University, advances reasons for considering the construction of the proposed dam likely to prove detrimental to public health. A protest is also entered against the alleged secrecy in which the proposals were prepared and formulated, and finally a call is made for a mixed committee of native and foreign

engineers, "free from all bias," to investigate the matter thoroughly on account of its vital importance to the welfare of the whole country.

THE paper by W. L. Cheney on the measurement of hysteresis values when using high magnetising forces, which has just been published by the U.S. Bureau of Standards (Paper No. 383), will be of interest to all engaged in magnetic research. When employing ordinary methods it is extremely difficult to get the accurate values of the remanent induction and the coercive force owing to what has been called magnetic viscosity. This probably also slightly affects the author's results. His method is a modification of the isthmus method, and consists essentially of a du Bois electromagnet with flat pole-pieces separated by an air-gap and pierced coaxially so that a rod may be inserted. The magnetic force and the induction are measured by suitable coaxial test coils. Magnetic forces up to 2500 gausses were employed. Quenching eutectoid steel (0·85 per cent. carbon) in oil lowered the remanent induction, but considerably increased the coercive force. Experiments were made on the K.S. magnet steel prepared by Prof. Honda, and the high coercive force of 200 gausses was obtained when the specimen had been magnetised with 800 gausses.

AN uncommon piece of work is described in *Engineering* for August 13 in the form of a long wooden jib for a derrick crane designed and constructed for the Admiralty during the war by the Imber Court Engineering Works, Thames Ditton, Surrey. The crane, with a 50-ft. post, had to be capable of raising a 3-ton load up to a platform 100 ft. high. The jib was 135 ft. long from the centre of the bottom pin to the centre of the rope-wheel, and the wooden construction adopted resulted in a jib being produced of one-third the weight and having a higher factor of safety than steel would have given. Including the rope-wheel and end casings, the jib complete weighed only 2 tons 13 cwt. The jib was built up of four corner-posts, each post being made of nine laminations of Oregon pine glued together with waterproof glue. The jib was divided into panels by struts, also of Oregon pine, and each panel had diagonal bracing, both longitudinal and transverse; these bracings were composed of stranded piano-wire. The struts were fixed to the corner-posts by welded steel clamping boxes, to which the diagonal braces were also connected by means of bolts on which the wire was wound. The bolt-heads were formed with teeth, with which two spring pawls engaged, so that turning the bolt tightened the wires and slacking back was prevented by the pawls.

THE concluding volume—the sixth—of the Scientific Papers of the late Lord Rayleigh is to be published by the Cambridge University Press in the spring of next year. It will range over the period 1911–20. Among the other forthcoming publications of the Cambridge University Press is "The Spectrum of Nova Geminorum II.," by F. J. M. Stratton. It will constitute vol. iv., part i., of the Annals of the Solar Physics Observatory, and is promised for the end of the present year.

Our Astronomical Column.

DISCOVERY OF A NOVA IN CYGNUS.—Mr. W. F. Denning, of Bristol, writes that on the evening of August 20 he observed a star previously unknown to him in the northern region of Cygnus. He has made it a practice during the last few years of carefully searching for these objects while he has been watching for meteors. The object when discerned on August 20 was of about $3\frac{1}{2}$ magnitude, and its rough position was in R.A. 19h. 56m. and declination $53\frac{1}{2}°$ N. It formed a little triangle with the stars ψ and *d* (20) Cygni. On referring to star-charts, etc., Mr. Denning quite failed to identify the object in question, and therefore concluded it to be a new star.

The position of the nova in the Milky Way is in accordance with past experience, for nearly all past novæ have been in the Milky Way or on its borders.

Mr. Denning saw the present object again on August 21 in the openings between swiftly passing clouds, and it appeared of about the same brightness as on the previous night, but only hurried glimpses were obtainable.

On August 22 the brightness was estimated=2·8 mag., and on August 23, 2·2 mag., so that its light is increasing.

PARALLAX OF THE B-TYPE STAR BOSS 1517.—Mr. J. Voûte recently announced a large parallax and proper motion for this star. Mr. A. J. Roy showed, however, that the true proper motion in R.A. was only one-tenth of Mr. Voûte's value, being $-0{\cdot}023''$; that in declination is $+0{\cdot}129''$. Mr. Voûte has recomputed the parallax with this value, and finds $0{\cdot}048''$, which is in good accord with Kapteyn's hypothetical value $0{\cdot}033''$.

The star is one of the nearest of the B stars, being at about the same distance as Achernar. Its chief interest lies in its surprisingly low absolute magnitude for a B-type star, its apparent visual magnitude being 5·9. According to Mr. R. E. Wilson, of the D. O. Mills Observatory, the radial velocity is +102 km./sec., or +83 corrected for the sun's motion. The position for 1910 is R.A. 6h. 0m. 59·436s., south decl. 32° 10′ 10·91″.

PUBLICATIONS OF THE ASTRONOMICAL LABORATORY AT GRONINGEN, NO. 29.—This is a further instalment of Prof. J. C. Kapteyn's valuable researches on the stellar system. He summarises the large amount of new material that has become available since he first took up the subject, and shows that the time is appropriate for a fresh investigation of the secular parallaxes of stars of different magnitudes and spectral classes. The secular parallax is defined as the angle subtended at the star by the unforeshortened annual motion of the sun. Assuming its speed to be $19\frac{1}{2}$ km./sec., then annual parallax=sec. par.×0·243. The following values are found for the variation of parallax with galactic latitude: From latitude 90° to 40°, parallax=1·17 of mean; from 40° to 20°, 0·96 of mean; and from 20° to 0°, 0·87 of mean.

Many investigators have found discordant values of the declination of the solar apex as derived from stars of different magnitudes. Prof. Kapteyn is inclined to attribute this to imperfect elimination of magnitude equation in declination from the catalogues employed, since he makes the discordance very small.

Prof. Kapteyn emphasises the importance of separating stars of different spectral type in these investigations. "In view of the great range of absolute magnitude according to type, he says that the grouping of all types is like making a single statistical investigation of the

whole animal kingdom, from the elephant to the flea, instead of dividing them into species.

The following table gives the mean secular parallaxes for different magnitudes and spectral types, the former being visual on the Harvard scale:

Mag.	B stars	A stars	F stars	G stars	K stars	M stars
	"	"	"	"	"	"
1·0	0·138	0·253	0·591	0·627	0·362	0·172
2·0	0·0921	0·170	0·392	0·422	0·241	0·116
3·0	0·0622	0·115	0·267	0·285	0·163	0·0786
4·0	0·0422	0·0780	0·182	0·192	0·110	0·0537
5·0	0·0285	0·0526	0·123	0·129	0·0749	0·0364
6·0	0·0192	0·0355	0·0827	0·0876	0·0506	0·0244
7·0	0·0130	0·0240	0·0560	0·0599	0·0342	0·0163
8·0	0·0087	0·0161	0·0379	0·0403	0·0231	0·0108
9·0	0·0059	0·0109	0·0254	0·0271	0·0156	0·0073

The small values near the end of the final column show that these distant M stars are giants nearly equivalent to the B stars in absolute magnitude. On the other hand, the M stars mentioned on page vii. as being 17½ magnitudes fainter than the B stars are dwarfs.

Universities, Research, and Brain Waste

THIS is the subject of a presidential address by Prof. J. C. Fields to the Royal Canadian Institute, Toronto, on November 8, 1919. It contains a review of the relations which must subsist between universities and research and between research and the progress of the world in civilisation, and it opens up so many aspects of these questions which are debatable that for that very reason it ought to be read extensively. Though, on the whole, Prof. Fields's views are consolatory to us in the Mother Country, they also show how much has yet to be done in England, as in other countries, to prevent or reduce the waste of potential brain power in the generations to come. Conditions are now greatly improved whereby the educational net is able to select out of the masses of population the individuals whose mental qualities deserve and, in the interest of the community, require due cultivation, but for the full benefit we must wait a generation or two.

It is premature to make comparisons between the different races and nations in respect to intellectual qualities, but it seems to be incontestable that the Germans have for generations been distinguished by their respect for learning and intellectual achievement, and this is illustrated by the way in which during the war their highly trained men were preserved from too much risk. The Allies, on the other hand, took no special care to protect and preserve such men as Moseley, who was allowed to sacrifice his life in Gallipoli. Such waste is, as Prof. Fields says, a tragedy of the first order. But there is similar waste going on every day in the neglect to give every boy of promise an open road to the university and the right kind of teaching when he gets there.

It is a question open to discussion whether the opportunity to do research lies only in a university career. The successive great discoverers at the Royal Institution in London, from Davy and Faraday onwards, and men like Joule, who was a brewer, and others unconnected with educational institutions, rise at once to mind. But it certainly is true that in the universities the example, the methods, and the spirit of research should be found associated with the teaching in every faculty and in every department.

Prof. Fields was severe on the constitution and government of the American universities, but while it appears to be true that most of the professors there are overworked and that the standard of attainment among the graduates is inferior to those of the universities of Europe, the work that has been done at Johns Hopkins, Baltimore, and Harvard Universities must not be forgotten. Probably the next generation on both sides of the Atlantic will profit by the interchange of visits by representatives of the higher educational institutions and by the opportunities for exchange of students, both graduate and undergraduate. It is probable also that there is still great ignorance, especially among the masses of the people in all countries, of the fact that the most potent factor in bringing the world out of barbarism to its present better condition of life has been *science*. "Is it not," Prof. Fields says, "of the first importance that every boy and girl should be made aware of this fact?" With that object in view modern history requires to be taught by teachers better qualified than in the past.

The Sun as a Weather Prophet.

SOME forty years ago Prof. Langley, while engaged on his early bolometric work on the sun, grasped the principle that, inasmuch as solar radiation is *the* governing factor in world meteorology, it should ultimately become possible to forecast weather changes, so soon as sufficient information had been obtained in regard to the mechanism of the radiation effect, by continuous observation of the intensity of radiation. Gradual improvement in instruments and methods has enabled his successors to state positively that the so-called "solar constant" is subject to variations of long and short period, and of late years determined attempts have been made, chiefly by the Smithsonian observers, to trace the meteorological changes that may fairly be attributed to these variations. It is clear that there are, from time to time, disturbing factors of apparently terrestrial origin—for instance, the eruption of Mount Katmai, in Alaska, in 1912, brought a promising summer to an abrupt and chilly close in mid-July; but it is becoming more and more probable that the Smithsonian investigation is on the right lines, and will give definite aid to forecasting, at any rate in tropical and sub-tropical regions.

Publication No. 2544 of the Smithsonian Miscellaneous Collections (vol. lxxi., No. 3) is devoted to a full statement of the case as regards Argentina, Chile, and Brazil in connection with regular observations of solar radiation at the new solar observatory at Calama, in Chile. Clear evidence is provided by the temperatures found at Buenos Aires that high values of solar radiation are followed by maximum values of temperature at an interval of nearly eleven days. The interval is not the same for lower maxima of radiation, and the amount of lag appears to be connected with the latitude of outbreaks on the sun, but more remains to be explained than the solar rotation will cover. The lag is also not the same for all stations considered. Twenty such were chosen in the countries mentioned, and differences are noted in the intensities as well as in the intervals, and also between the effect of longer and shorter waves. The observations do not cover every day, so that the correlation is probably not so good as it would be if complete data could be provided. The change due to a variation of 1 per cent. in the solar radiation appears to range between 0·2° C. and 0·8° C. in the tropics; in the temperate zones the effect, though less direct, is greater, even exceeding 2° C. at some stations.

Having thus obtained satisfactory evidence that, with the exception of the diurnal and annual varia-

tions due to the rotation and revolution of the earth, all weather changes are caused chiefly by variation of solar radiation, the next step was clearly to bring it into practice for forecasting. This has now been done for Central Argentina with promising results, but the ideal of daily measures of solar radiation is not yet attainable, because more stations are required. Even at Calama, which is nearly cloudless, good observations are not always possible on account of haze.

The concluding paragraph of the report states: "The ideal arrangement for this solar work would be to carry it on in co-operation with the Smithsonian Astrophysical Observatory. If the work at several widely separated observatories could be directed by one capable institution, so that the methods could be uniform and the results comparable, and then if it could be collected and weighted at the central office before cabling to the various weather surfaces of the world, probably a complete and reliable day-to-day record of the solar changes could be obtained which would be of the greatest value to practical meteorology. If the Smithsonian Institution is unable or unwilling to do this work, then it is hoped that observatories will be established by several countries and some direct method of exchange instituted." W. W. B.

Cotton Industry Research.

THE British Cotton Industry Research Association, which was incorporated in June, 1919, has just issued its first annual report. The association is comprised of 1408 individual members representative of all branches of the cotton industry, and its council includes not only members of the great firms engaged in the industry, but also those representing the various associations of operatives.

The association has appointed as its director of research Dr. A. W. Crossley, who took up his duties last Easter. A large mansion some five miles from the Manchester Exchange, standing in 13½ acres of ground, has been bought for the purposes of the association, to which it is proposed to add extensive buildings, for which it is intended to raise a special fund of 250,000*l*., to accommodate the various departments of chemistry, physics, colloids, botany, and technology, and to appoint as heads of these departments highly qualified men of science. In order to bring to the notice of the members all available information of work done in the past, Dr. J. C. Withers, of London, has been appointed to direct the abstracting and indexing of scientific and technical matters in connection with the Records Bureau, and the council, in co-operation with the Textile Institute, has arranged for the publication of abstracts from English and foreign papers dealing with matters relevant to the textile industries. It is proposed to establish an extensive library of standard scientific works of reference and of scientific and technical journals. A scheme of education falls within the scope of the association, and already certain Oldham and other mills have arranged to provide scholarships in some branch of science for students who are desirous of becoming members of the staff of the association. The plan of research is intended to cover the qualities of the cotton cuticle and the influence thereon of different reagents employed in mercerisation, bleaching, etc.; the effect of reagents on the strength and elasticity of the fibre, yarn, and fabric; the character of the change due to mercerisation; the nature of tendering in the various types of fibre; the variation in the physical properties of sized yarn, with change in the colloid properties of the material used; the action of the dyeing process, with critical regard to the established purity of materials; the nature of the dye solution, and the chemical change in the latter during the dyeing process; finally, the devising of methods for obtaining exact information as to the length of staple, the behaviour of fibres under stress and strain, the degree of variation in counts and in the diameter of yarn, relative twist, the degree of resistance of yarn to weaving friction, etc. Arrangements have been made for co-operation with the Empire Cotton-Growing Committee (Board of Trade), and in co-operation therewith the Research Association has made a grant of 250*l*. for 1919–20 to a student of botany at Oxford in aid of botanical research in the subject of cotton-growing. The joint committee has likewise arranged for two other students to take up like work in the ensuing session. The income of the association is derived from a call upon the members to the extent of about 9000*l*. and a Government grant from the Department of Scientific and Industrial Research of 7000*l*. The Department has shown the greatest interest and given all possible help in the furtherance of the objects of the British Cotton Industry Research Association.

Sugar Cultivation in India.

THE existing world-shortage of sugar lends special interest to all experimental work directed towards any advance in the quantity and quality of this essential crop. Sugar-growing and its improvement are attracting an increasing amount of attention in India, the area under sugar-cane having risen from 2,184,801 acres in 1909–10 to 2,808,204 acres in 1917–18, while in addition the date-palm and palmyra-palm occupied 184,412 acres in the latter period ("Agric. Statistics for India," 1917–18, vol. i.). More than half the sugar-cane is grown in the United Provinces, chiefly Agra, and the Punjab accounts for about one-fifth. Palm-sugar, on the other hand, is chiefly associated with Madras, Bengal, and Upper Burma, little being produced elsewhere. The output of sugar for 1918–19 was 2,337,000 tons (Report on Progress of Agriculture in India for 1918–19), but, as this was insufficient to meet home requirements, a large quantity had to be imported. Before the war India was able to produce a surplus of sugar for export, but as this can no longer be done the Government is investigating the possibility of reorganising and developing the sugar industry of the country, and a strong committee has been appointed to determine future policy in this direction. Dr. Barber, who has worked much on the problem, considers that a case has been made out for the foundation of an Imperial Sugar Bureau, of which the "whole duty will be to collect and collate the results obtained in various directions, and thus be in a position to assist the isolated efforts in different parts of the country with sound advice, based on experience gained by a general survey of the work done in India now and in the past and that accomplished in other countries" (Annual Report of the Board of Scientific Advice for India, 1918–19).

Throughout India much work is being done on the improvement of the sugar-cane and on the selection and breeding of varieties suitable for different conditions and localities. At the cane-breeding station at Coimbatore, under the direction of Dr. Barber, a large number of hybrids have been raised and are under observation, some of the seedlings proving very resistant to red rot and smut, two of the most serious

diseases of sugar-cane. As a result of this work it has been possible to pass out a number of seedlings for further testing on a large scale in different places. The trial of new varieties is also carried out in Madras and the United Provinces, for the old ones which have hitherto been grown are rapidly losing favour with the cultivators, and it is necessary to find new and improved varieties to replace them. When imported canes are used it is necessary constantly to renew the stock from the country of origin. Soil and climate have a marked effect on the canes, and varieties that are markedly superior in one area often deteriorate rapidly in quality if transferred elsewhere, and, consequently, experience gained from experimental work in one part of the cane-growing tract is often of doubtful value for another area. This fact makes a strong argument for an increase in the number of sugar research stations in order that the most suitable stocks may be determined for the various localities.

Newly broken up land does not give very satisfactory results, but it should be left for at least a year before planting. If a proper rotation of crops is used, an increase of as much as 5 tons of cane per acre can be obtained. Manurial experiments in Assam have shown that the use of phosphatic fertilisers gives an average increase of 2–3 tons per acre, and in Pusa it is found that rape-cake, farmyard manure, and nitrate of soda can all be utilised with profit. In Madras it is estimated that careful manuring will raise the crop from 25 to 30 tons per acre, which is probably the limit for that particular climate.

Apart from the actual selection and cultivation, special attention is being devoted to the handling of the sugar-cane in order to avoid damage and deterioration. Canes are often stored by windrowing, and tests made over a period of several months show that this does not lead to any appreciable decrease in the quality or amount of sugar obtainable from equal weights of the original and the windrowed cane, but that after a certain time has elapsed deterioration sets in. Experiments suggest that this deterioration is not dependent upon the length of storage, but that the falling off of the quality is probably due to a seasonal rather than a biological factor.

Special methods have been devised at Coimbatore (*Agric. Journ.*, India, xv., part ii.) for the transport of cane for short distances and overseas. In the latter case it is advised that the pieces of cane be pickled in Bordeaux mixture for a short time in order to avoid the introduction of disease from one locality to another. Charcoal-dust, teak sawdust, and wood-shavings all make satisfactory packing materials.

Attention is now being directed to the use of the palmyra-palm as a sugar producer (*Agric. Journ.*, India, xv., part i.). Toddy is made in Bihar from the sweet juice of this palm, but as less than 10 per cent. of the trees are tapped it is probable that the manufacture of sugar would pay. The process of tapping needs special care to obtain the best results. The tips of the flowering stalks are cut off after the male and female inflorescences have been squeezed or otherwise injured to irritate them into producing a good flow of sweet sap. The insides of the collecting pots are coated with lime to preserve the juice and prevent fermentation. The crude sugar obtained from this juice contains lime, which is removed by passing a current of carbon dioxide through the sugar solution until all the lime is precipitated, and a cheap white sugar can then be prepared. It is suggested that as the production of sugar from the wild date-palm has so far been satisfactory, it would be well worth while to give the palmyra-palm industry a fair trial.

W. E. Brenchley.

University and Educational Intelligence.

Liverpool.—The title of emeritus professor of engineering has been conferred upon Prof. H. S. Hele-Shaw.

Mr. R. S. Glennie, of the Battersea Polytechnic, has been appointed chief lecturer in pharmaceutics at the Royal Technical College, Glasgow.

The Treasury has made to the University College at Swansea a grant of 5000*l.* in a lump sum towards expenses, and also an annual grant of another 5000*l.*

Reference has already been made in these columns to the establishment of a new Department of Aeronautics at the Imperial College at South Kensington. This addition to the work of the college was initiated by the generous action of Sir Basil Zaharoff, who endowed the University of London chair of aviation known as the Zaharoff chair, tenable at the college, to which Sir Richard Glazebrook was appointed with the duty of directing the new department. A comprehensive scheme of instruction and training, mainly post-graduate in character, has been arranged for next session, beginning in October, including special sections in aeronautical engineering, meteorology, and navigation, and with the valuable co-operation of the Air Ministry the services of a distinguished staff of experts have been engaged. Apart from the director with his great experience of this work at the National Physical Laboratory, Sir Napier Shaw will be professor of meteorology and Mr. Leonard Bairstow professor of aerodynamics; Mr. A. J. Sutton Pippard will deal with the structure and strength of aircraft, and Mr. A. T. Evans with aircraft engines. Courses of lectures will also be given dealing respectively with airships and with navigation, while arrangements are in hand for special instruction in air-cooled engines, high-compression engines, dopes, instruments, wireless telegraphy, and similar subjects. Subject to certain necessary restrictions, it has also been arranged that students of the department will carry out part of their practical training in one or other of the Government establishments concerned with aeronautics.

The Bureau of Education at Washington has just issued a Bulletin (No. 11) giving statistics relating to school systems in the United States for the year 1917–18. The bulletin is concerned with elementary and secondary education only, and is an elaborate document covering 153 pages octavo, accompanied by 62 tables of statistics and by 49 maps and diagrams illustrative of the various aspects and conditions of primary and higher education, other than university and professional, in the several States. From the figures set forth it would appear that the total population of the States has increased from 38·2 millions in 1870 to 105·4 millions in 1918, and that the children of school age between five and eighteen have increased from 12 to 27·2 millions, and the school enrolment from nearly 7 to nearly 21 millions; whilst the pupils in the high schools, who numbered 80,000 in 1871, were about 1,700,000 in 1918. The number of teachers employed was 650,709, being 105,194 men and 545,515 women, whose average salary in 1918 was 635 dollars, as compared with 189 dollars in 1870. The percentage of scholars enrolled of school age between five and eighteen was 75 in 1918 and 57 in 1870, largely due to better teaching and supervision, a more suitable course of study, transportation of pupils, and improved economic and general condi-

tions. The total value of school buildings, sites, and equipment is stated to be of the vast total of nearly 2,000,000,000 dollars. The school dollar income is spent as follows: 3·3 cents on general control, 58·2 on instruction, 15·5 on new buildings and grounds, and 23 miscellaneous. The average length of the school year is stated to be 160 days, though the cities usually provide a school term of nine months. More than 6,000,000 children attend school, on an average, less than five months in each year. Great diversity exists throughout the States, due to climatic conditions, the scattered nature of much of the population, racial differences, and varying educational legislation, which largely accounts for the striking differences which prevail. The bulletin is well worthy the close attention of educational authorities in this country.

Societies and Academies.

LONDON.

Physical Society, June 25.—Sir W. H. Bragg, president, in the chair.—Dr. J. H. **Vincent**: The origin of the elements. The atomic weights are regarded as the weighted mean values of the atomic weights of the isotopes of the elements; but it is assumed that, as a rule, the atomic weight is near that of some one isotope. Figures and tables are drawn up showing how this accounts for the values of a large number of atomic weights, if one also assumes that the weights and positions in the periodic table of any isotope are conditioned by laws similar to those holding in the recognised radio-active families. The elements are all supposed to be derived from parent elements by processes known to occur in actively radiating families, but their radio-activity is not, in general, detectable by the usual means owing to the velocity of expulsion of the particles being low. The possibility of the reversibility of some radio-active processes is regarded favourably. The various difficulties in connection with the views advocated are discussed, and some suggestions for experiments made. Finally, the theory is used to explain the so-called laws of the atomic weights of elements of low atomic weight, and the shape of the curve obtained when the atomic weights are plotted against Moseley's numbers.—W. H. **Wilson** and Miss T. D. **Epps**: The construction of thermo-couples by electro-deposition. The method, which was devised to overcome the difficulty of making satisfactory soldered joints between the elements of thermopiles having a large number of closely packed junctions, consists in using a continuous wire of one of the elements and coating those parts of it which have to form the other element with an electrolytic deposit of another metal. If the conductivity of the latter is considerably greater than that of the former, and a fairly thick sheath is deposited, a thermo-couple is produced which is not appreciably impaired in efficiency by the short-circuiting effect of the core. Constantan wires coated with either copper or silver sheaths were found to be suitable for most purposes.—J. **Guild**: The use of vacuum arcs for interferometry. The paper discusses the relative merits of short and long mercury arcs for this work, and points out that the defect of the former is due to the broadening of the spectrum lines consequent on the high vapour pressure within the lamp. It is shown that by attaching a condensing bulb to the lamp, so as to prevent excessive rise of vapour pressure, the short lamp can be made practically as good as the long one as regards sharpness of lines, while still being of much greater intrinsic brightness.—S. **Butterworth**: The maintenance of a vibrating system by means of a triode valve. This paper gives a mathematical analysis of the arrangement, previously described by Eccles, whereby the vibrations of a tuning-fork are maintained by means of a triode.

PHILADELPHIA.

American Philosophical Society, April 24.—Dr. G. E. Hale, vice-president, in the chair.—Prof. E. W. **Brown**: The problem of the evolution of the solar system.—W. H. **Wright**: Certain aspects of recent spectroscopic observations of the gaseous nebulæ which appear to establish the relationship between them and the stars. The paper summarises in non-technical terms the evidence afforded by a study of the stellar condensations in the planetary or small gaseous nebulæ which are shown to be spectroscopically identical with stars of the Wolf-Rayet group (Pickering's Class O). A brief account is given of some of the present-day conceptions of stellar evolution for the purpose of indicating the somewhat critical nature with respect to these ideas of the relationship indicated.—Prof. E. P. **Adams**: The Einstein theory. The extension of the principle of relativity and the resulting revision of the concepts of space and time led to Einstein's interpretation of gravitation as a property of space itself when modified by the presence of matter.—Dr. L. A. **Bauer**: The results of geophysical observations during the solar eclipse of May 29, 1919, and their bearing upon the Einstein deflection of light. The present paper gives the results of a special study of the cause of the non-radial effects of the light deflections observed by the British expedition at Sobral, Brazil. It is shown that these non-radial effects may be completely accounted for by incomplete elimination of differential refraction effects in the earth's atmosphere. The same cause may apparently also explain why the observed radial deflections of light exceeded, on the average, by about 14 per cent. the amounts predicted on the basis of the Einstein law of gravitation.—Prof. J. B. **Whitehead**: The high-voltage corona in air. The paper describes the nature of the corona and recent studies of the laws governing its appearance in high-voltage circuits. Its influence as a limiting factor in long-distance transmission occurs through deterioration of insulation and a leakage loss of power between the high-voltage lines. The appearance of corona on a clean round wire is very sharply marked, and may be used for the measurement of high alternating voltages to a degree of accuracy not heretofore possible.—Prof. D. C. **Miller**: The velocity of explosive sounds. Most of the experiments were made in connection with 10-in. and 12-in. rifles, though a few were made with 6-in. and 8-in. guns. The amount of powder charge and the value of the internal pressure developed in the gun are taken into account. The sounds were received by means of specially constructed carbon-granule microphones, those for use near the gun being of unusually rugged construction, while others were of a very sensitive type. The records were made by a specially constructed moving-film camera in connection with a string-galvanometer capable of recording from six stations simultaneously, of the type used by the U.S. Army for sound-ranging. Meteorological observations were made by special observers in the distant stations and on the field near the guns at the time of the experiments, and continuous records were made at the Proving Ground Headquarters and at the United States Weather Bureau Station. These observations covered temperature, barometric height, humidity, wind velocity, and wind direction. Measurements were also made of the velocity of the sound at a series of stations located on a line at right angles to the line of fire and on a line at 45° to one side of the line of fire. Heretofore there has been a general

impression that explosive sounds travel much farther than do ordinary sounds, the velocity being, perhaps, several times the normal velocity. These experiments show conclusively that the velocity at a distance of ... ft. from a 10-in. gun is about 1240 ft. per second, or 22 per cent. above normal; at 200 ft. from the gun the velocity is only about 5 per cent. above normal. For all distances above 500 ft. from the gun the velocity of the explosive sound from the largest-sized gun is practically normal.—Dr. H. C. **Hayes**: The U.S. Navy MV-type of hydrophone as an aid and safeguard to navigation.—Dr. A. E. **Kennelly**: The transient process of establishing a steady alternating electric current on a long line from laboratory measurements on an artificial line. It is known that the current and voltage do not build up steadily and continuously, but advance by little jumps which occur at regular short intervals of time, accompanying successive reflections of electromagnetic waves from one end of the line to the other. There is presented in this paper a number of observations which have been secured photographically of the rise of voltage and current on a long artificial electric power transmission line in the laboratory, and have compared the observed rates of growth with those which are indicated by theory with a fairly satisfactory agreement.—N. W. **Akimoff**: The strephoscope.—Prof. R. S. **Dugan**: New features in the eclipsing variable U Cephei. (Prof. W. B. Scott, president, in the chair.)—Prof. E. N. **Harvey**: Animal luminescence and stimulation. The production of light by animals is due to the burning or oxidation of a substance called luciferin in the presence of an enzyme or catalyst called luciferase. Light production by animals differs from light produced by combustion in that the oxidation product of luciferin, oxyluciferin, can be easily reduced to luciferin, which will again oxidise with light production. The reaction is reversible, and appears to be of this nature: luciferin+O $\rightleftarrows$ oxyluciferin+H_2O. The difference between luciferin and oxyluciferin lies probably in this: that the luciferin possesses two atoms of hydrogen, which is removed to form H_2O when the luciferin is oxidised. The H_2 must be added to re-form luciferin. Not only is it most efficient so far as the radiation (being all light) it produces is concerned, it is also most economical so far as its chemical processes are concerned. The above reactions can be demonstrated in a test-tube with a mixture of oxyluciferin, luciferase, and ammonium sulphide. The ammonium sulphide is probably represented in living cells by reducing enzymes or reductases. If such a test-tube is allowed to stand, oxyluciferin is reduced to luciferin, which will luminesce only at the surface of the fluid in the test-tube in contact with air. When the tube is agitated so as to dissolve more oxygen of the air, the liquid glows throughout. Even a gentle knock or "stimulus" to the tube is sufficient to cause enough oxygen to dissolve to give a momentary flash of light which is strikingly similar to the flash of light given by luminous animals themselves on stimulation. This suggests that when we agitate a luminous animal, or when the luminous gland-cells of a firefly are stimulated through nerves, with the resultant flash of light, in each case the stimulus acts by increasing the permeability of the surface-layer of the cells to oxygen. This then upsets an equilibrium involving the luciferin, luciferase, oxyluciferin, oxygen, and reductase within the cell, with the production of light and the formation of more oxyluciferin. So long as the luminous cell is resting and unstimulated, the tendency is for reduction processes to occur and luciferin to be formed. It must be pointed out that not all sorts of stimulation can be explained in this way, as the stimulation of muscles or nerve-fibres may take place in the complete absence of oxygen.—Prof. G. H. **Parker**: The phosphorescence of Renilla. During the day Renilla cannot be excited to phosphoresce, but at night on stimulation it can be made to glow with a beautiful golden-green light. The light is produced in wave-like ripples that spread out from the spot stimulated and run over the upper surface of the animal. They travel at a relatively slow rate that agrees with that at which the nervous impulses of the animal travel. Hence it is concluded that the phosphorescence of Renilla is under the control of the nerve-net of the animal, which apparently pervades the whole colony.—Prof. W. M. **Wheeler** and I. W. **Bailey**: Feeding habits of Pseudomyrmine ants. Examination of the mouth of the larva reveals a singular hitherto undescribed organ, evidently used for reducing the food-pellet to such a finely divided state that it can, when acted upon by the digestive juices of the stomach, yield a certain amount of nutriment which the worker-ant could not extract from it while it was in the infrabuccal pocket. This larval organ may be called the trophorhinium. In all Pseudomyrmine larvæ, and in many larvæ of the other sub-families, except the Dorylinæ and Cerapachyinæ, the trophorhinium is beautifully developed, although in many ants (Ponerinæ) it must be used for comminuting parts of insects given directly to the larvæ by the workers. In its development the trophorhinium bears a strange resemblance to the stridulatory organs of the petiole and post-petiole of many adult ants.—Dr. A. E. **Ortmann**: Correlation of shape and station in fresh-water mussels. It has been found that for certain species more swollen specimens are found down-stream in the larger rivers and more compressed specimens more up-stream, and that in the intermediate stretches of a river these extremes are connected by gradual transitions.—Prof. H. F. **Osborn**: Evolution principles deduced from a study of the even-toed Ungulates known as Titanotheres.—Prof. W. B. **Scott**: The Astropotheria.—B. F. **Howell**, jun.: The Middle Cambrian beds at Manuels, Newfoundland, and their relations. These beds are of special scientific interest because they contain large numbers of unusually well-preserved fossils, which prove that the creatures that swarmed in the waters then covering much of what is now New England, south-eastern Canada, and south-eastern Newfoundland were of practically the same sort as those living in the seas which at the same period washed over many parts of Scandinavia and the British Isles. North America has probably been joined to Europe in this way several times in the geological past, so that the animals living in the coastal waters could spread from one hemisphere to the other.—Prof. W. H. **Hobbs**: (1) The Michigan meteor of November 26, 1919. (2) The glacial anticyclone and the blizzard in relation to the domed surface of continental glaciers.

ROME.

Reale Accademia dei Lincei, March 7.—A. Ròiti, vice-president, in the chair.—Q. **Majorana**: Gravitation, viii.—O. **Chisini**: Analytic representation of the fold of a surface by a series of fractional powers of two variables.—U. **Cisotti**: Integration of the equation of wave-motion in a deep canal, ii. The equation of the free surface is determined.—O. **Onicescu**: Newtonian fields in the neighbourhood of a given vectorial field. An application of Levi-Civita's notion of harmonics in the neighbourhood of an assigned function. The author deduces the lamellar and solenoidal magnetisation which gives rise to a given magnetic field, and applies the result to deal with the existence and unique nature of the magnetisation in soft iron

—L. Tonelli: Researches on primitive functions, iii. —V. Sabatini: Leucitic lavas of the volcano of Roccamonfina. This deals mainly with the composition of the spurs, and particularly with the presence of leucite.—B. Peyronel: A parasite of the lupin, *Blepharospora terrestris.* In December, 1919, plants of lupin were received infected with this parasite from Pantano and Pratolongo, near the Lake of Regillo. It appears to kill the plants, completely destroying the tubercles of the roots. The question is raised as to whether the parasite is of American origin, but the author considers it probably an indigenous type that has recently become destructive.—T. Levi-Civita: Harmonics in the neighbourhood of an assigned function. The problem is reduced to the determination of the Newtonian function having the given function as its density.—R. Perotti: Nitrogen of the cyanic group in manures. A contribution to the determination of the mechanism of action of cyanic nitrogen in vegetable nutrition and the conditions for its utilisation.—M. Ascoli and A. Fagiuoli: Sub-epidermic pharmacodynamic experiences, ii. The action of pituitrin is discussed. The limit of reactivity in normal subjects fluctuates about a dilution of 500. —L. Cattolica: Obituary notice of G. Dalla Vedova, professor of geography in the University of Rome.—Sig. Baglioni: The life and work of the late Luigi Luciani, professor of pathology at Parma from 1875 to 1880, and afterwards professor of physiology at Siena, Florence, and Rome in succession.

March 21.—F. D'Ovidio, president, in the chair.—Q. Majorana: Gravitation, ix. Gravitation may be partly absorbed by matter, and this absorption may give rise to heat. Bodies will then have two kinds of mass, apparent and real, and the real density of the sun will then be three times its apparent or astronomical density. An experimental test is being arranged at Turin for studying the action of 100 quintals of lead on a small central mass.—O. Chisini: Contact of curves of diramation for an algebraic function of two variables.—M. De Angelis: Crystalline forms of nitrodichloroacetanilide. This substance is dimorphic, modifications α and β both being monoclinic and prismatic, the former with $a:b:c=$ 1·1507 : 1 : 1·1348 and $\beta=66^\circ\ 23'$, the latter with the values 1·5792 : 1 : 1·0952 and $62^\circ\ 23{\cdot}5'$. The second form is decidedly unstable, and when left in the mother-solution, or even dried, it transforms in time into an aggregate of crystals of the stable phase.—R. Perotti: Measure of the ammoniating power of soils. The best conditions for employing the method of solutions are 10 c.c. solution of peptone of 1·5 per cent. in test-tubes, adding 5 c.c. of a mixture formed of 50 grams of earth in 500 grams of water; cultivation for four days in a thermostat at 20°–25° C., and determination of ammonia by distillation on oxide of magnesia.—M. Ascoli and A. Fagiuoli: Sub-epidermic pharmacodynamic experiences, iii. Certain alkaloids, such as atropine, pilocarpine, muscarine, physostigmine, morphine, eserine, nicotine, cocaine, and scopolamine, which offer a cutaneous reaction of œdematogenous type, are referred to.
